Glossary and list of abbreviations

Term or abbreviation	Definition
ANOVA	Analysis of Variance
ARUP	Arup Pty Ltd
Baseline Surveys	The four Baseline Surveys completed as part of the Kamay Ferry Wharves seagrass pre-construction monitoring program
Buffer Area	Temporary construction footprint comprising a 15 metre buffer around the Construction Footprint (permanent)
Cardno	Cardno Pty Ltd, now Stantec
CHIRP	Compressed High-Intensity Radiated Pulse
Construction Footprint	Permanent construction footprint for the wharf structures
CPCe	Coral Point Count with Excel extensions
DoD	Depth of Disturbance
DPI	The NSW Department of Primary Industries
EPBC Act	<i>Environment Protection and Biodiversity Conservation Act 1999</i>
EIS	Environmental Impact Statement
EIS study area	Study area adopted in the Project EIS (TfNSW 2021a)
FM Act	<i>Fisheries Management Act 1994 (NSW)</i>
<i>Halophila</i>	Seagrass species from the genus <i>Halophila</i> , predominantly <i>Halophila ovalis</i> but may also include <i>Halophila decipiens</i>
Inner Transect	Transect extending across monitoring sites (PB-K05, PB-K06, PB-K07, PB-K08) along the inner edge (from the shoreline) of the largest seagrass bed at Kurnell, with monitoring sites positioned at increasing distances from the Construction Footprint
IOD	Indian Ocean Dipole
Monitoring sites	Monitoring sites established as part of the Kamay Ferry Wharves seagrass pre-construction monitoring program
Niche	Niche Environment and Heritage Pty Ltd
nMDS	Non-metric Multidimensional Scaling
Outer Transect	Transect extending across monitoring sites (PB-K01, PB-K02, PB-K03, PB-K04) along the outer edge (from the shoreline) of the largest seagrass bed at Kurnell, with monitoring sites positioned at increasing distances from the Construction Footprint
PCoA	Principle Coordinates Analysis
PERMANOVA	Permutational multivariate ANOVA
<i>Posidonia</i>	The seagrass species <i>Posidonia australis</i>
Project	The reinstatement of the ferry wharves at La Perouse and Kurnell in Botany Bay (the Project)
Project Boundary	Project area as delineated by Transport for New South Wales
Reference sites	Reference sites are identified within the Seagrass Monitoring Program as a basis to compare against trends or patterns identified among the potential impact sites. As it cannot be established that the reference sites are free from any other sources of

Term or abbreviation	Definition
	impact or stressors, other than the project construction, they cannot be considered 'control' sites.
Seagrass Monitoring Program	The Kamay Ferry Wharves seagrass pre-construction monitoring program
Survey Area	Survey area for the current assessment, incorporating subtidal areas of seagrass habitat within 50-100 metres of the Project Boundary
Shoot (seagrass)	A shoot is considered the section of seagrass from the sheath up and may consist of one or various leaves
TfNSW	Transport for New South Wales
The Ecology Lab	The Ecology Lab Pty Ltd
<i>Zostera</i>	Seagrass species from the genus <i>Zostera</i> , predominantly <i>Zostera capricorni</i> but may also include <i>Zostera muelleri</i>

1. Introduction

1.1 Project background

Transport for New South Wales (TfNSW) is proposing to reinstate the ferry wharves at La Perouse and Kurnell in Botany Bay (the Project). The Project was classified State Significant Infrastructure (SSI) under the NSW Planning Framework and is a controlled action under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) (EPBC Act referral 2020/8825).

The Project would allow for an alternative to the road connection between La Perouse and Kurnell. Its main purpose would be to operate a public ferry service for visitors and the community. In addition, the Project would provide supplementary temporary moorings for tourism-related commercial vessels and recreational boating.

A Marine Biodiversity Assessment Report was prepared as part of the Environmental Impact Statement (EIS) (TfNSW 2021a). This report identified that the Project would result in impact to seagrasses, including the endangered *Posidonia australis* ecological community and population in Botany Bay, listed under the *Fisheries Management Act 1994* (FM Act). Impacts on seagrasses will include some direct losses of seagrass within the permanent Construction Footprint and associated temporary 15 metre buffer (Buffer Area) from shading, along with disturbances during construction works and ongoing operation of the wharves and ferries (TfNSW 2021a). In addition, a large and significant bed of *P. australis* seagrass located adjacent to and beyond the Project Boundary at Kurnell is considered of ecological significance to the population in Botany Bay and an important conservation requirement of the Project.

The Project Boundary for the Baseline Surveys encompasses the Construction Footprints and Buffer Areas at Kurnell and La Perouse, as well as a broader area including the known seagrass areal extents in proximity to the Project works. The Baseline Surveys have been completed within this Project Boundary.

Investigations of seagrass in or nearby the Project Boundary at La Perouse and Kurnell have found seagrass bed areal extent and morphology (i.e. shoot density, leaf length) to be highly temporally and spatially variable, especially off Silver Beach at Kurnell. In some places, areal extent was wider than previously mapped (Larkum and West 1990, Otway and Macbeth 1999, NSW DPI 2021). At both La Perouse and Kurnell, several vessel moorings within or adjacent to the Project Boundaries are likely to be having, and may have ongoing, impacts on seagrass areal extent in these areas. At Kurnell in particular, exposure to large easterly swells is considered a major driver of temporal changes in seagrasses within the Project Boundary and expansion of the adjacent large *P. australis* bed to the east (Niche 2022b). The *Zostera* and *Halophila* species of seagrass are typically much more widely distributed within the Project Boundary. These species colonise new areas much earlier and more quickly than *P. australis* and undergo much greater temporal fluctuations in areal extent, density and dominance, which is typically driven by environmental conditions and establishment from the seed bank within the locality (Waycott et al 2014).

1.2 Project description

The Project includes the construction of two new wharves, one at La Perouse and one at Kurnell. The wharves would be designed to accommodate ferries up to 40 metres in length, along with recreational and commercial vessels up to 20 metres in length.

The total construction period is anticipated to take up to 13 months and will require the following:

- Use of a temporary crane and rig platform (onshore) to install nearshore piles and piers at La Perouse.

- Construction of a causeway to provide piling shoot access to install nearshore piles and piers at Kurnell.
- Repositioning and anchoring of a jack-up barge to provide a platform for construction works for the wharves.

1.3 Monitoring purpose

The EIS (TfNSW 2021a) has identified the need for establishment of a Seagrass Monitoring Program that includes Baseline Surveys and is designed to determine construction and operation impacts associated with the Project.

The pre-construction monitoring requires four Baseline Surveys and two years of data collection to obtain a sufficient baseline dataset. It is required to determine baseline areal extent and condition of seagrasses both within and adjacent to the Project Boundary to guide final offset requirements and provide a foundation by which any changes in the adjacent large *P. australis* bed following construction can be detected. The purpose of the Seagrass Monitoring Program is to identify any large-scale changes in seagrass composition and areal extent within the Project Boundary and monitor for any changes in the adjacent large bed of *P. australis* at Kurnell during construction and operation that may be attributable to the Project.

To date, this Seagrass Monitoring Program has successfully completed the four Baseline Surveys over two years, as required by the EIS, to establish a sufficient baseline to determine construction and operation impacts. This report presents the findings of the fourth baseline monitoring survey (referred to as Baseline 4) completed in summer 2022/23 (section 4). The report also details temporal trends or changes that have occurred across the seagrass beds throughout the baseline monitoring period (complete baseline dataset) (section 5).

1.4 Baseline monitoring to date

This report details the methods and findings of the Baseline 4 survey completed in December 2022 (summer 2022/23). The Baseline 1 survey was completed in winter 2021 (Niche 2021a), Baseline 2 in summer 2022 (Niche 2022a) and Baseline 3 in winter 2022 (Niche 2022b), Table 1.

Table 1: Baseline monitoring surveys completed to date

Survey	Season	Survey date	Period	Reference
Baseline 1	Winter 2021	July – September 2021	Pre-construction	Niche (2021a)
Baseline 2	Summer 2022	February – April 2022	Pre-construction	Niche (2022a)
Baseline 3	Winter 2022	August – September 2022	Pre-construction	Niche (2022b)
Baseline 4	Summer 2022/23	December 2022	Pre-construction	Current report

2. Review of existing information

2.1 Past and present development in the locality

A public ferry service operated between the previous ferry wharves (located within the current Project Boundary) at La Perouse and Kurnell intermittently for 75 years until the wharves were damaged in 1974 by a heavy storm.

At both La Perouse and Kurnell, several vessel moorings located within or adjacent to the Project Boundaries are likely to be having, and may have ongoing, impacts on seagrass areal extent in these areas. A large seawall has been established at Frenchmans Beach immediately north of the Project Boundary at La Perouse, with wave refraction from this structure contributing to extensive shoreline erosion in 2022 (Niche 2022a).

There has also been a significant level of landscape modification in the wider locality of Botany Bay and across its catchment since European settlement. In recent times, major development projects within Botany Bay and along its shoreline include the:

- Port Botany Expansion project.
- Kurnell Ports and Berthing Facility, Prince Charles Parade, Kurnell and Botany Bay.
- Kurnell Desalination Plant and Associated Infrastructure.

The Port Botany Expansion project EIS (URS 2003) identified the following categories of human activities and potential effects relating to aquatic habitats and ecosystems within Botany Bay:

- Modification of aquatic habitats including port and airport developments, establishment of groyne fields at Lady Robinsons Beach and Silver Beach, stream realignment of waterways entering the Bay, dredging to facilitate navigation and fill material extraction as well as the widespread establishment of hard surfaces along intertidal and subtidal areas.
- Shipping activities and operations, including the potential for spillages, ballast water exchange, and the introduction of exotic species on ship hulls.
- Water quality and sediment contamination from industrial activities, resultant from catchment-wide activities as well as specific industrial contamination within the Bay.
- Fishing activities, both indirectly through habitat modification to support fishing activities and directly by removing individuals across a wide range of species.
- Introduction of exotic species associated with commercial shipping including toxic dinoflagellates, as well as *Caulerpa taxifolia* (an aquatic pest species under Schedule 1 of the *Biosecurity Regulation* 2017) for which the origin or source of introduction is unknown.

These human activities and developments have resulted in modifications to aquatic habitats ecosystems within Botany Bay.

Towra Point Aquatic Reserve is a marine protected area. The reserve is situated on the southern shores of Botany Bay, approximately 4 kilometres from the Project Boundary at Kurnell. The Towra Point Aquatic Reserve encompasses the majority of seagrass, mangroves and saltmarshes within Botany Bay (URS 2003). Previous capital works construction programs have altered erosion patterns at Towra Point, leading to the loss of seagrass beds. The key driver of change has been identified as dredging within the entrance to Botany Bay leading to increasing wave energy, height and direction at Towra Point (The Ecology Lab 2003).

Seagrass within Botany Bay

The aquatic ecological assessment undertaken by The Ecology Lab (2003) as part of the Port Botany Expansion project EIS presents a comprehensive summary of previous studies of seagrass within Botany Bay. The Ecology Lab (2003) identified four species of seagrass as being reported from Botany Bay, including *P. australis* along the southern shoreline, *Zostera capricorni* and *Halophila ovalis* along both the northern and southern shores, as well as *Halophila decipiens* occurring in Quibray Bay. The study compared the results of several studies completed between 1942 and 1995, finding fluctuations in the total area of seagrass beds in Botany Bay through time, including changes in the areal extent of individual seagrass beds throughout the bay. Key drivers of these changes in areal extent were identified as residential and industrial development, realignment of the Cooks River, and dredging to facilitate ship passage to and from the Caltex Oil Refinery terminal wharf altering wave patterns (The Ecology Lab 2003).

2.2 Seagrass areal extent and EIS findings

Chapter 10 of the Project EIS (TfNSW 2021a) described the seagrass community within the EIS study area prior to the commencement of this Seagrass Monitoring Program.

La Perouse

Seagrass areal extent within the La Perouse study area was described as patchy, with *Halophila* spp. being the main species. *Halophila* spp. was found throughout most of the soft sediment, particularly in the deeper areas. *Z. capricorni* was mainly confined to the southern corner along Frenchmans Bay and was intermixed with *Halophila* spp. Some small, isolated patches of *P. australis* were identified amongst the other seagrass species in the shallower areas closer to the shore.

Seasonal fluctuations in the density of *Halophila* spp. within Frenchmans Bay were observed between the two EIS seagrass surveys completed in autumn and spring 2020.

Kurnell

Seagrass areal extent was widespread throughout the study area at Kurnell, typically occurring in water depths of between one and five metres, with *P. australis*, *Z. capricorni* and *Halophila* spp. all identified within the study area. *Z. capricorni* and *Halophila* spp. were found in the deeper areas towards the east of the study area, with *Z. capricorni* also abundant in shallower waters close to the shoreline.

P. australis was typically confined to a large dense bed on the western side of the proposed wharf footprint in shallow water, with smaller isolated patches amongst other seagrasses in the shallow waters close to the shoreline to the east.

Seasonal fluctuations in the density of *Halophila* spp. were also observed at Kurnell between the EIS seagrass surveys completed in autumn and spring 2020 and attributed to storm damage occurring in winter 2020. A review of aerial imagery found that that the seagrass condition, areal extent and extent near Kurnell frequently changes due to storm events, as well as due to more regular seasonal fluctuations.

2.3 Baseline monitoring summary to date

Three Baseline Surveys were completed prior to Baseline 4. These were Baseline 1, completed in winter 2021 (Niche 2021a), Baseline 2 in summer 2022 (Niche 2022a) and Baseline 3 in winter 2022 (Niche 2022b).

Significant weather events during the baseline monitoring period in 2022

Above average rainfall conditions occurred throughout autumn and into winter 2022, with a significant weather event, including above average rainfall and a large easterly swell, occurring in July 2022, impacting upon Baseline 3 (Niche 2022b). This followed above average rainfall over summer and a large easterly swell

in early March (Niche 2022a). Rainfall associated with these events resulted in major flood levels in the Georges River and Cooks River that lowered salinities, increased turbidity levels and reduced light availability due to high sediment loads, for extended periods. The large and powerful easterly swells associated with these weather events also resulted in significant coastal erosion, further increasing sedimentation and reducing water quality, and directly impacting on some areas. This, at times, has included direct disturbance to more exposed areas to the east around Kurnell. At La Perouse, although very protected, refraction of waves back into Frenchmans Bay has also resulted in significant seabed and shoreline disturbances (Niche 2022b). At Kurnell in particular, exposure to large easterly swells is considered a major driver of temporal changes in seagrasses within the Project Boundary and the adjacent large *P. australis* bed to the east. The results collected for Baseline 2 and Baseline 3 therefore need to be interpreted with consideration to the significant weather conditions experienced throughout 2022, which have been more broadly attributed to the prevailing La Niña weather pattern.

Seagrass areal extent and density

Overall seagrass areal extent and density declined between Baseline 1 and Baseline 3 (Niche 2022b). These declines amounted to a reduction of greater than 50% during that period of time and was in most part due to the declining areal extent of *Halophila* and/or *Zostera* seagrass beds. Where *Halophila* and/or *Zostera* seagrass beds persisted in Baseline 3, the seagrass density also substantially declined to coverages of less than 1% at the majority of the monitoring sites. In Botany Bay, these *Zostera* and *Halophila* beds are known to be highly variable in areal extent, species composition and density (Larkum and West 1990). The significant weather events described above have coincided with known seasonal decreases in biomass of *Zostera* during the winter months (West 2000). Although less documented, seasonal fluctuations in *Halophila* in Botany Bay (Cummings Pers. Obs) is also likely responsible for much of these large reductions in seagrass areal extent and cover detected during Baseline 3.

Declines in *P. australis* areal extent were also described, but of a much lesser magnitude, and in most part were confined to Kurnell (Niche 2022b). The lesser impact of these weather events on *P. australis* areal extent is likely reflective of the deeper and much greater biomass of rhizomes of this species, which likely provide greater resilience to such disturbances. Although *P. australis* areal extent changes were considered relatively minimal in Baseline 3, a strong trend of reduced biomass was evident, with fewer shoot densities and reduced leaf lengths at the majority of sites. This is likely reflective of the poor environmental conditions for growth as a result of water quality disturbances such as reduced available light (Larkum 1976) and physical disturbances from sedimentation and seabed disturbance during and/or after these weather events.

Seagrass areal extent and biomass within the Project Boundary substantially decreased between Baseline 1 and Baseline 3, with the majority of this reduction associated with *Halophila* and *Zostera* beds. Changes in *P. australis* areal extent are much lesser and more variable, although a reduction in biomass does appear to be more evident. These changes are likely the result of seasonal reductions in biomass and weather-event-related disturbances.

3. Methods

3.1 Overview

The Seagrass Monitoring Program has been developed to align with the requirements identified within the Marine Biodiversity Offset Strategy (TfNSW 2021b). The program includes four survey approaches:

- Seagrass mapping: Seagrass areal extent mapping of seagrass composition and density within the Survey Area;
- Drop camera surveys: Collection of photo quadrats from within *Halophila* and *Zostera* seagrass beds for quantitative analysis of seagrass composition and density;
- *Posidonia* bed monitoring: Diver-based quadrat surveys of seagrass morphology (composition, biomass and condition) in *P. australis* beds (typically >100 m²); and
- *Posidonia* patch monitoring: Seagrass morphology surveys of smaller *P. australis* patches (typically <100 m²).

Specific monitoring sites are shown for La Perouse in Figure 1, and for Kurnell in Figure 2. A full list of site codes and GPS coordinates can be found in Appendix 1.

Four types/extents of survey area relative to the proposed construction works are defined within the overall area covered by the monitoring program (Figure 1 and Figure 2) to inform the assessment:

- Construction Footprint - refers to the permanent construction footprint for the wharf structures and is the primary area of anticipated direct impacts to seagrass. Direct impacts occurring within the Construction Footprint are likely to be permanent, due to the nature of the structures.
- Buffer Area - refers to the temporary construction footprint comprising a 15 m buffer around the Construction Footprint. Direct impacts to seagrass may occur within this area during construction, however no permanent structures will remain post-construction. Ongoing indirect impacts such as vessel wash and shading from vessels may also occur within this area.
- Project Boundary – refers to the Project area as delineated by TfNSW.
- Survey Area – refers to the area of survey for the current assessment, incorporating subtidal areas of seagrass habitat within 50-100 metres of the Project Boundary and including the Construction Footprint and Buffer Area.

3.2 Survey frequency and timing

Surveys are undertaken twice per year (biannually) with consideration of winter and summer seasons – this being the fourth baseline survey. The Baseline Surveys, including previous surveys associated with the EIS completed to date, are summarised in Table 2.

Table 2: Baseline Surveys and previous EIS surveys

Survey	Season	Survey dates	Reference
EIS survey surveys			
EIS survey	Winter 2020	June 2020	(Niche 2020a)
EIS survey	Winter 2020	August – September 2020	(Niche 2020b)
EIS survey	Summer 2020	December 2020	(Niche 2021b)
Pre-construction Baseline Surveys			
Baseline 1	Winter 2021	July – September 2021	Niche (2021a)
Baseline 2	Summer 2022	February – April 2022	Niche (2022a)
Baseline 3	Winter 2022	July – August 2022	Niche (2022b)

Survey	Season	Survey dates	Reference
Baseline 4	Summer 2022/23	December 2022	Current report

The Baseline 4 survey was completed throughout the month of December 2022 (summer 2022/23). Dates for each survey method undertaken are listed in Table 3.

Table 3: Baseline 4 (Summer 2022/23) seagrass monitoring survey dates

Methodology	Survey date Kurnell	Survey date La Perouse
Seagrass mapping	01/12/22 - 13/12/22	01/12/22 - 13/12/22
Drop camera surveys	21/12/22	21/12/22
Posidonia Bed Monitoring	06/12/22 – 09/12/22	07/12/22
Posidonia Patch Monitoring	06/12/22 – 09/12/22	07/12/22

3.3 Baseline master dataset

Since collection of Baseline 4 field data, all data associated with the program has been consolidated into a master dataset and subject to additional quality assurance prior to statistical analysis.

The master dataset has been provided as an additional electronic appendix to this report (Appendix 3) and forms the basis of all data summary and analysis presented within this report.

The master dataset should be considered the most accurate and up-to-date dataset to be used for future iterations of monitoring program planning, sampling and reporting.

3.4 Seagrass mapping

3.4.1 Objective

To determine a baseline measure of seagrass composition and areal extent within the Survey Area.

3.4.2 Survey areas

La Perouse

Subtidal areas of seagrass habitat within 50-100 metres of the Project Boundary (Figure 1).

Kurnell

Subtidal areas of seagrass habitat within 50-100 metres of the Project Boundary (Figure 2).

3.4.3 Methodology

Preliminary desktop works included review of the most recent Nearmap imagery (captured: 02/08/2022) and previously-prepared polygons of seagrass areal extent from previous surveys (Niche 2021a, Niche 2022a, Niche 2022b).

Previously-developed layers and associated Nearmap imagery were displayed in a GIS-based field collection device with GPS accuracy of approx. +/-3m. Verification of habitat was recorded on the device as point data using customised applications within the Field Maps Software package.

Visual observations to verify the seabed habitat were made using a combination of towed camera (Plate 1) transects through the Survey Area and spot observations using a bathoscope, drop camera or, in the cases of shallow areas and during periods of clear water, observation from the side of the boat. The towed camera was towed within 1 metre of the seabed and positioned so imagery was being provided from directly under the survey vessel where seagrass boundaries occurred or within ~2 metres of the stern of the

survey vessel when verifying larger uniform areas. The towed and drop cameras allowed for *in situ* field verification of mapping by providing video imagery live to the topside monitor on the survey vessel. The vessel sonar, which included CHIRP ClearVu and SideVu sonar that incorporates a thin, wide beam to provide clear images of structure and any larger seagrasses (with lengths of approximately 10 cm or greater) below the vessel, was also used to aid mapping and target seabed areas with structure, especially during periods of reduced water visibility.

Field verification survey effort within seagrass habitat inside the Survey Area consisted of collection of 3,311 points at La Perouse and Kurnell during the Baseline 4 survey, with no greater than 22.6 metres between two verification points.

Post-collection analysis of field verification points was undertaken using ArcGIS Pro software to construct an updated set of habitat polygons. The dataset depicting the areal extent and extent of seagrass and non-seagrass habitats was created from interpolated point observations collected on site. Each point was assigned a value for the habitat type (seagrass or non-seagrass) and seagrass habitats were assigned a density value (Low, Medium, High). Polygon data were interpolated by distance, with spatially-associated points forming distinct patches of habitat and density. The data were then cleaned to remove errors, and a manual verification and editing pass was conducted by the Niche GIS team to better align boundaries to those observed in recent, high-resolution Nearmap imagery. Finally, the data were verified for accuracy by the Ecology team and edited where required to depict more detailed field notes for small patches of *P. australis* habitat, especially within the Construction Footprint and associated Buffer Area.

3.4.4 Data analysis

The following calculations were made using GIS Software for La Perouse and Kurnell:

- Seagrass area within the Survey Area
- Seagrass area within the Project Boundary
- Seagrass area within the Construction Footprint
- Seagrass area within the 15-m Buffer Area around the Construction Footprint.

3.5 Drop camera surveys

3.5.1 Objective

To determine the baseline community composition and density of *Zostera*- and *Halophila*-dominated seagrass beds in the Project Boundary.

3.5.2 Survey area

Each baseline monitoring site comprised a circular area with a radius of 10 metres from a central point, amounting to a total area of 314 m².

La Perouse

Four drop camera monitoring sites were re-surveyed at La Perouse (Figure 1):

- Two (2) potential 'impact' sites (HZ-LP-01 & HZ-LP-02) within the Project Boundary, established during the Baseline 1 survey.
- Two (2) 'reference' sites (HZ-LP-03 & HZ-LP-04) outside the Project Boundary, established during the Baseline 1 survey.

Kurnell

Six drop camera monitoring sites were re-surveyed at Kurnell (Figure 2):

- Four (4) potential impact sites, two in deeper areas near the seaward end of the wharf (HZ-K-05 & HZ-K-06) and two nearer to the shore in shallower water (HZ-K-09 & HZ-K-10), established during the Baseline 1 survey.
- Two (2) reference sites (HZ-K-07 & HZ-K-08) outside the Project Boundary, established during the Baseline 1 survey.

3.5.3 Methodology

The centre point of each monitoring site was located using handheld GPS. Once located, a temporary float was positioned at the centre of the site. Each photo quadrat image was collected at a haphazardly-located position within 10 metres of the centre of the site.

Photoquadrats were collected using a drop camera custom designed for seagrass surveys (Plate 1) that can obtain a high-resolution image of a known area of the seabed. Care was taken each survey to avoid collecting photographs of the seabed that overlapped.

Photos that were of poor quality, taken when the frame was not stationary on the seabed, duplicates or identified to have overlapping imagery were removed from the dataset. A subset of 30 photos were then randomly selected from the dataset and uploaded into Coral Point Count with Excel Extensions (CPCe) Software for analysis. Within the CPCe software a digital photoquadrat of each image was created to form an area of 0.25 m² (0.5 x 0.5 m) and 30 points were randomly overlaid on the image. Under each point a habitat category was assigned (Table 1).

Table 4: Major and sub-categories used with the CPCe Software.

Major category	Sub-categories
SEAGRASS (S)	Halophila, Zostera, Posidonia
ALGAE (A)	Macroalgae, Turfing Algae, Epiphytic Algae (when identified to be attached to the seagrass)
CORAL (C)	Hard Coral, Soft Coral
SUBSTRATE (SU)	Gravel & Shell, Rock & Rubble, Sand & Silt
OTHER BIOTA (OB)	Sessile Invertebrate
TAPE WAND SHADOW (TWS)	Tape, Wand (frame), Shadow (insufficient resolution), Macroalgae Wrack, Seagrass Wrack, Other Debris.

3.5.4 Data analysis

For each photoquadrat percent cover was calculated for each of the categories (except Tape, Wand and Shadow) and sub-categories (Plate 1), while Tape, Wand and Shadow were excluded from the percent cover calculations. Summaries for each site, including means and standard errors (SEs), were then calculated for:

- Seagrass cover by type;
- Sediment/silt cover;
- Turfing algae cover; and
- Epiphytic algae cover.

3.5.5 Statistical Analysis

Statistical analysis was performed using the PERMANOVA+ for Primer statistical software package (Anderson *et al.* 2008). PERMANOVA is a permutational approach to ANOVA that has a number of advantages over traditional statistical methods. The PERMANOVA procedure was used for both univariate (single variable) and multivariate (many variables) analyses. For univariate analyses parameters were

investigated using the Euclidean distance matrix, while the multivariate analyses were based on Bray-Curtis similarities. Pairwise comparisons were performed to further investigate any significant results identified in the PERMANOVA for factors/terms of interest. In the case where the number of unique permutations for a particular test was less than 100, Monte Carlo probability values were used to assess the significance of the test as outlined by Anderson *et al.* (2008). The significance level was set at $p < 0.05$ for all statistical tests.

For multivariate datasets such as the full set of percent cover data collected via CPCe here and then analysed using multivariate PERMANOVA, Principal Coordinates Analysis (PCoA) can be used to provide a graphical representation. The PCoA analysis itself provides a measure of the amount of variation in the data that can be captured by the first two axes. Vector overlays based on the Spearman's Correlation Coefficients are added to the graphical output base to display the strongest drivers of differences. The PCoA routine allows for the multivariate dataset to be visualised using metric multidimensional scaling. This approach is more appropriate than traditional uses of non-metric Multidimensional Scaling (nMDS) when PERMANOVA is applied, as it models the actual dissimilarities of interest that provide a direct projection of the points considered using PERMANOVA (Anderson *et al.* 2008).

Spatial and temporal patterns in differences among the of *Zostera*- and *Halophila*-dominated seagrass beds were investigated using a three-factor design (Table 5) in the first instance. The three-factor design allowed for and considered seasonal effects. Following three-factor analysis, the Season term was excluded and a simplified two-factor design (Table 5) applied when:

- The p values associated with terms involving the Season factor (i.e., both Se and Se x Si) were greater than 0.25, as suggested by Winer *et al.* (1991) and Underwood (1997) as a conservative approach to pooling interaction terms and/or discarding main effects terms.
- When plots of data (for univariate analyses) did not show any seasonal patterns.

Where the simplified two-factor design was applied, it allowed for focused investigation of differences among the sequence of Surveys irrespective of Season.

Statistical analyses focused on temporal changes and included:

- Univariate PERMANOVA for Total Seagrass Cover.
- Multivariate PERMANOVA and PCoA (full data set and centroids) using the subcategories (Table 4) that included any records across the four surveys. Note: As the Epiphytic Algae subcategory was collected with Turfing Algae in the Baseline 2 survey, these two sub-categories were combined for these analyses.

Table 5: Experimental design applied to statistical analyses of the drop camera data.

3.6 *Posidonia* bed monitoring

3.6.1 Objective

To determine the baseline community composition, biomass (density and leaf lengths) and condition of *P. australis* seagrass beds (>100 m²) with potential to be impacted during construction and operation.

3.6.2 Survey area

Each monitoring site comprised a circular area with a radius of 5 metres from a central point, amounting to a total area of 79 m².

La Perouse

Two *P. australis* bed monitoring sites were re-surveyed at La Perouse (Figure 1):

- One (1) potential impact site (PB-LP11) within the Project Boundary, established during the Baseline 1 survey.
- One (1) reference site (PB-LP12) outside the Project Boundary, established during the Baseline 1 survey.

Kurnell

Ten *P. australis* bed monitoring sites were re-surveyed at Kurnell (Figure 2):

- Eight (8) potential impact sites within the large extensive bed of *P. australis* to the west of the Project Boundary (PB-K01 to PB-K08), established during the Baseline 1 survey. These sites are positioned to allow for a gradient-based approach to monitoring for impacts to the large bed of *P. australis* to the west of the Project Boundary. Sites are located along two longshore transects (one near shore and one offshore) at a range of distances from the Construction Footprint (to represent approximate intervals of 75 m, 100 m, 150 m and 230 m).
- Two (2) additional potential impact sites within much smaller beds of *P. australis* inside the Project Boundary (PB-K09 and PB-K10), established during the Baseline 1 survey.
- Reference sites will be determined at the completion of the baseline monitoring. It is envisaged they will be selected from monitoring sites in the main western bed outside the Project Boundary (e.g., PB-K03, -K04, -K07 and -K08). There is also potential to include the most easterly site in the Project Boundary as a reference site, where impact from the proposal is considered unlikely.

3.6.3 Methodology

The centre point of each monitoring site was located using handheld GPS. Once located a temporary float was positioned at the centre of the site. Seagrass was surveyed via five 0.25 m² (0.5 x 0.5 m) quadrats, each haphazardly positioned within 5 metres of the centre of the site.

Within each quadrat the following data were recorded by experienced Scientific Divers:

- Shoot Density (counted from the sheath) for each seagrass species present (Note: *Halophila* also counted as shoots).
- Proportion (%) of shoots with visible sheaths for 10 randomly selected *P. australis* shoots.
- Visible Sheath Length for 10 randomly-selected *P. australis* shoots.
- Epiphyte Load (scored 1-5, see Appendix 2) for 10 randomly-selected leaves for each seagrass species present.

In addition to the above measurements a photograph was taken above each quadrat for archiving purposes.

3.6.4 Data analysis

Data calculations and summaries included means and SEs for the following:

- Shoot (*Posidonia*) count per 0.25 m².
- Leaf length (cm).
- Epiphyte load score.

In the cases of the Baseline 1 and 2 surveys, many seagrass sheaths for *P. australis* shoots were found to be covered by sediment and sheath measurements could not be obtained. For the purposes of the program it was deemed more appropriate to present sheath data as percent of shoots with visible sheaths rather than as measurements of sheath length. As such, sheath length is no longer recorded.

3.6.5 Statistical Analysis

Statistical analysis was performed using the PERMANOVA+ for Primer statistical software package (see Section 3.4.5).

Spatial and temporal patterns in differences among the *Posidonia* seagrass bed monitoring sites were investigated using a three-factor design (Table 6) in the first instance. The three-factor design allowed for and considered seasonal effects. Following the three-factor analysis, the Season term was excluded, and a simplified two-factor design (Table 6) applied when:

- The p values associated with terms involving the Season factor (i.e., both Se and Se x Si) were greater than 0.25, as suggested by Winer *et al.* (1991) and Underwood (1997) as a conservative approach to pooling interaction terms and/or discarding main effects terms.
- When plots of data (for univariate analyses) did not show any seasonal patterns.

Where the simplified two-factor design was applied, it allowed for focused investigation of differences among the sequence of Surveys irrespective of Season.

For analyses where the two-factor design could not be adopted (i.e., $p < 0.25$ for one or both of the terms involving Season), where appropriate the sums of squares and degrees of freedom for the lower interaction term (i.e., Su(Se) x Si) were pooled with those of the Residual term (i.e., where the p value for Su(Se) x Si was greater than 0.25 – Winer *et al.* 1991, Underwood 1997).

Statistical analyses focused on temporal changes and included:

- Univariate PERMANOVA for *Posidonia* shoots.
- Univariate PERMANOVA for *Posidonia* leaf length.
- Univariate PERMANOVA for *Posidonia* epiphyte ranking.
- Multivariate PERMANOVA and PCoA (full data set and centroids) for shoots of all three seagrass types (*Posidonia*, *Zostera* and *Halophila*).

For *Posidonia* Bed monitoring sites positioned along both the Inner and Outer Transects, regression analyses were also performed using the Excel Data Analysis Toolpack Add-on to investigate any linear relationships between response variables (seagrass parameters) and distance from the Construction Footprint Outer Transect. Regression analysis was done by Survey and for all Surveys combined, where a linear relationship between distance and a response variable (e.g. shoot density, leaf length) of interest was identified in the charts.

Table 6: Experimental Design applied to statistical analyses of data from the *Posidonia* beds.

Term	Type	Levels

Su(Se) x Si	Interaction Term	
TWO-FACTOR DESIGN		
Survey - Su	Random	4 Baseline surveys
Site - Si	Random	2 Sites at La Perouse, 10 Sites at Kurnell
Su x Si	Interaction Term	

3.7 *Posidonia* patch monitoring

3.7.1 Objective

To determine the baseline community composition, biomass (shoot density and leaf lengths) and condition of *P. australis* seagrass patches (<100 m²) in close proximity to the Construction Footprint.

3.7.2 Survey area

Patches (<100 m²) of *P. australis* seagrass that met the following criteria were surveyed:

- Inside or within 15 m of the Construction Footprint.
- Shoot density of at least five shoots per 1 m².
- Has an extent of at least 10 m² and minimum width of 2 m.

La Perouse

Two *P. australis* patches were re-surveyed at La Perouse, established during the Baseline 1 survey (Figure 1):

- PP-LP-01: Approximately 10 m east of the 15 m buffer.
- PP-LP-02: Approximately 15 m east of the 15 m buffer.

Kurnell

Six *P. australis* patches were re-surveyed at Kurnell, established during the Baseline 1 survey. (Figure 2):

- PP-K-03: Approximately 15 m east of the 15 m buffer.
- PP-K-04: Inside the Construction Footprint and 15 m buffer.
- PP-K-07: Approximately 3 m west of the 15 m buffer.
- PP-K-08: On the western edge of the 15 m buffer.
- PP-K-09: On the eastern edge of the 15 m buffer.
- PP-K-11: On the eastern edge of the 15 m buffer (note that this site has a *Zostera* patch in the middle that is not sampled).

3.7.3 Methodology

The centre point of each monitoring site was located using handheld GPS. Once located a temporary float was positioned at the centre of the site. Seagrass was haphazardly surveyed via up to five 0.25 m² (0.5 x 0.5 metre) quadrats, each haphazardly positioned within 5 metres of the centre of the site.

Within each quadrat the following data were recorded by experienced Scientific Divers:

- Shoot density (counted from the sheath) for each seagrass species present (Note: *Halophila* counted as shoots).
- Leaf length of 10 randomly-selected leaves for both *Zostera* and *P. australis*.
- Percent of shoots with visible sheaths for 10 randomly-selected *P. australis* shoots.
- Epiphyte load (scored 1-5, see Appendix 2) for 10 randomly-selected leaves for each seagrass species present.

In addition to the above measurements a photograph was taken above each quadrat for archiving purposes.

3.7.4 Data analysis

Data calculations and summaries included means and standard errors for the following:

- Shoot (Shoot *Posidonia*) count per 0.25 m²
- Leaf length (cm)
- Percent of shoots with visible sheaths
- Epiphyte load score.

3.7.5 Statistical Analysis

Statistical analysis was performed using the PERMANOVA+ for Primer statistical software package (see Section 3.4.5)

Temporal patterns in differences within the *Posidonia* seagrass patches were investigated for each patch separately using a two-factor design (Table 7) in the first instance. The two-factor design allowed for and considered seasonal effects. Following two-factor analysis, the Season term was excluded and a simplified one-factor design (Table 7) was used when:

- The p value associated with Season was greater than 0.25, as suggested by Winer *et al* (1991) and Underwood (1997) as a conservative approach to pooling interaction terms and/or discarding main effects terms.
- When plots of data (for univariate analyses) did not show any seasonal patterns.

Where the simplified one-factor design was applied, it allowed for focused investigation of differences among the sequence of Surveys irrespective of Season.

Statistical tests were limited to temporal changes in *Posidonia* shoot counts at each patch, which required a univariate PERMANOVA.

Table 7: Experimental Design applied to statistical analyses of data from the *Posidonia* patches

Term	Type	Levels
TWO-FACTOR DESIGN		
Season - Se	Fixed	2 Seasons - Winter and Summer
Survey(Season) - Su(Se)	Nested/Random	2 Baseline surveys nested in each Season

Term	Type	Levels
ONE-FACTOR DESIGN		
Survey	Random	4 Baseline surveys

3.8 Limitations

The monitoring program has been identified as subject to the following limitations:

- Seagrass mapping is subject to the accuracy of the GPS-enabled equipment utilised during the surveys (up to ± 5 metres) and dependent on the limitations of aerial photo rectification and registration, which is also limited to the resolution and clarity of the most recent imagery available.
- The significant weather events and associated rainfall in 2022 presented a limitation to the program. The effect of these significant weather events was most acute during the Baseline 2 and Baseline 3 surveys and had the following implications:
 - Disrupting the ability to sample on consecutive days and under similar conditions within the survey. This resulted in some survey methods being completed at different times across the survey due to the limited survey windows within climatic seasons (Table 2).
 - During Baseline 2, the seagrass mapping was completed prior to the drop camera surveys, resulting in some apparently contradictory results, such as mapped seagrass no longer being present or highly diminished (due to the significant weather events) at the time of the drop camera surveys (Niche 2022a).
 - Seagrass mapping at La Perouse during Baseline 2 was also impacted by adverse weather, resulting in the delayed collection of some data following the frequent weather events. Seagrass areal extents mapped during these two separate survey days are likely to have been different because of the high rainfall events and storms that occurred between those two days (Niche 2022a).
- Depth of Disturbance (DoD) rods were established at each of the *Posidonia* bed monitoring sites during Baseline 1 (Niche 2021a). Following significant weather events in summer 2021, 80% of the DoD rods were missing or disturbed at the time of Baseline 2 (Niche 2022a). Given the flooding events that occurred in the locality and lack of reliability in the data, the methodology was considered unlikely to be suitable for this program and discontinued (Niche 2022a).
- Seagrass area calculations presented in this report are based upon the GDA2020 MGA56 coordinate system. Therefore, there may be minor discrepancies between areas presented in this report and those in Baseline 1 and 2 (Niche 2022a, 2022b), which are based upon the GDA94 MGA56 coordinate system. The area calculations presented in this report and included in the master dataset (Appendix 3) should be considered to be the most accurate and up to date results.

The methods of data collection and analysis are considered to be comprehensive to the aims of the baseline monitoring program and the program is not subject to any significant limitations.

4. Results – Baseline 4 (summer 2022/23)

4.1 Seagrass areal extent

During the Baseline 4 monitoring surveys completed in summer 2022/23, a combined total of 30,880 m² of seagrasses was mapped within the Project Boundaries at La Perouse and Kurnell (Table 8, Figure 1, Figure 2). This total included 740 m² of seagrasses within Kurnell Construction Footprint (no seagrass was present within the La Perouse Construction Footprint) and an additional 3,137 m² within the two Buffer Areas combined. Outside of the Project Boundaries, an additional 48,130 m² of seagrass was mapped within the broader Survey Area at Kurnell, and 11,386 m² of seagrass at La Perouse.

At Kurnell, 740 m² of seagrass was mapped within the Construction Footprint, with 3086 m² of seagrass occurring within the Buffer Area. At La Perouse, no seagrass was recorded within the Construction Footprint, with only 51 m² of seagrass mapped within the Buffer Area.

The majority of seagrass mapped within the Project Boundaries at La Perouse and Kurnell combined was comprised of *Halophila* beds and *Zostera / Halophila* beds (Table 8, Figure 1, Figure 2). Sand or silt were the dominant habitats mapped within the Project Boundaries.

Table 8: Areal extent of seagrass types mapped at Kurnell and La Perouse during Baseline 4 (summer 2022/23) within the Survey Area, Project Boundary, Construction Footprint (area of direct impacts) and associated Buffer area (area of indirect impacts).

Further data are provided in section 5.1 and Appendix 4.

4.2 *Zostera* and *Halophila* seagrasses

The key results for seagrass cover of *Zostera*- and *Halophila*-dominated beds in the Baseline 4 survey (summer 2022/23) are summarised below, with further data provided in Appendix 5:

- At Kurnell at least one species of seagrass was detected at eight of the ten *Zostera*- and *Halophila*-dominated beds, with no seagrass detected at sites HZ-K06 and HZ-K07 (Figure 3).
- At La Perouse there appeared to be no clear difference in overall seagrass cover between monitoring sites inside (HZ-LP01 and HZ-LP02) and those outside the Project Boundary (HZ-LP03 and HZ-LP04) (Figure 3).
- No *P. australis* seagrass was detected at any of the monitoring sites for both locations.
- *Zostera* and *Halophila* cover was very low at La Perouse (0.2% – 0.7%). Where present, *Zostera* and *Halophila* cover at Kurnell was higher, ranging between 4.4% and 25.5%).
- The monitoring sites for *Zostera*- and *Halophila*-dominated beds closer to shore at Kurnell (HZ-K09 and HZ-K10) recorded higher seagrass cover than the sites further from the shore (Figure 3). These beds closer to the shore feature relatively greater covers of *Zostera* than the other beds, with *Zostera* cover particularly high at HZ-K10.

Figure 3: Baseline 4 (summer 2022/23) – mean *Halophila* and *Zostera* seagrasses cover (+/- SE total seagrass cover).

The results for sediment cover, turfing algae and epiphytic algae during Baseline 4 are presented in Table 9. The key findings include:

- At La Perouse, sediment cover was high in Baseline 4, ranging between 62.1% - 97.6% cover. Sediment cover at Kurnell was also generally high, ranging between 46.4% - 98.9% cover.
- Turfing algae was absent at almost all sites, with the exception being HZ-K-05 at Kurnell, where it was present in minor amounts.
- Epiphytic algae was recorded at two of the four sites at La Perouse (HZ-LP-02 and HZ-LP-03). In contrast, epiphytic algae was recorded at all monitoring sites at Kurnell.

Table 9: Mean covers of sediment, turfing algae and epiphytic algae at each site during Baseline 4 (summer 2022/23).

Site	Epiphytic algae (EA) (%)		Turfing algae (TA) (%)		Sediment (SS) (%)	
	Mean	Standard error	Mean	Standard error	Mean	Standard error
HZ-LP-01	0.0	0.0	0.0	0.0	82.3	3.8
HZ-LP-02	2.6	1.0	0.0	0.0	62.1	5.2
HZ-LP-03	0.1	0.1	0.0	0.0	94.3	1.2
HZ-LP-04	0.0	0.0	0.0	0.0	97.6	0.8

HZ-K-07	1.2	0.5	0.0	0.0	98.7	0.5
HZ-K-08	7.0	2.5	0.0	0.0	88.9	3.7
HZ-K-09	26.8	2.5	0.0	0.0	59.4	2.9
HZ-K-10	28.1	2.6	0.0	0.0	46.4	3.7

4.3 *Posidonia* seagrass

4.3.1 Shoot density

The key results from the shoot density surveys at *Posidonia* bed monitoring sites (PB-) and *Posidonia* patch monitoring sites (PP-) in Baseline 4 (summer 2022/23) (Table 10, Figure 4) are summarised below:

- All three species of seagrass were detected at the majority of monitoring beds and patches.
 - *P. australis* was present at all monitoring beds and patches.
 - *Zostera* was present at almost all monitoring beds and patches, with the exception being patch PP-LP01.
 - *Halophila* was absent at monitoring beds PB-K10, PB-LP11 and PB-LP12.
- Average *P. australis* shoot density in *Posidonia* beds at La Perouse and Kurnell ranged between 4.5 shoots per 0.25 m² (PP-LP01) and 35.2 shoots per 0.25 m² (PB-K08).
 - The highest *P. australis* densities were recorded at monitoring sites towards the centre of the main *Posidonia* bed at Kurnell (southwest of the Project Boundary), with the smaller *Posidonia* beds within the Project Boundary and to the east recording relatively lower densities.
 - At La Perouse the monitoring site within the Project Boundary (PB-LP-11) had a lower *P. australis* shoot density (7.0 shoots per 0.25 m²) than the reference site (PB-LP12) (14.6 shoots per 0.25 m²).
 - No *Halophila* seagrass was recorded at either of the La Perouse monitoring beds during this survey.

Further data are provided in sections 5.3 and 5.4, and Appendix 5.

Table 10: Average shoot density recorded at *Posidonia* bed monitoring sites and patches during Baseline 4.

4.3.2 Leaf lengths

The key results for leaf lengths in *Posidonia* bed monitoring sites and patches in the Baseline 4 survey (Table 11) are summarised below:

- Average leaf lengths for *P. australis* were somewhat variable across monitoring sites at Kurnell, ranging between 11.7 cm (PB-K03) and 38.6 cm (PB-K09). Those monitoring beds with lowest average leaf lengths (PB-K03, PB-K04) occur towards the outer edges of the main seagrass bed located to the west of the Construction footprint (Figure 2), while those within this main bed recorded relatively higher average leaf lengths (PB-K05, PB-K06, PB-K07, PB-K08).
- Average leaf lengths for *P. australis* at La Perouse were more consistent, ranging between 29.2 cm (PP-LP01) and 38.6 cm (PB-LP11).
- The average leaf lengths recorded for *Zostera* across both locations ranged between 3.3 (PP-K11) and 30.6 (PB-K03).

PP-LP02	5.2	29.2	2.0	1.8	3.5	100.0

Further data are provided in sections 5.3 and 5.4, and Appendix 5.

4.3.3 Seagrass sheaths

The average percentage of visible sheaths was found to be highly variable across the sites in Baseline 4 (Table 11). For *Posidonia* beds, PB-K07 recorded the highest average percentage of visible sheaths at 52.0%. A number of *Posidonia* beds recorded no visible sheaths (PB-K01, PB-K03, PB-K04, PB-K10, PB-LP11). Average percentage of visible sheaths was also found to be highly variable across *Posidonia* patches. The highest average percentage of visible sheaths among these monitoring patches was 100.0% (PP-LP02) and the lowest was 0.0% (PP-LP01).

4.3.4 Epiphyte cover

The epiphyte cover results for Baseline 4 (Table 11) show that epiphytic growth was typically higher on *P. australis* shoots than on *Halophila* or *Zostera*. The epiphyte cover scores across the *Posidonia* bed and patch monitoring sites ranged between 2.0 (PB-K11) and 4.5 (PB-K03) for *P. australis*. For *Zostera*, the range was between 1.0 (PB-K01 and PB-K10) and 2.3 (PB-K06, PB-K07, PB-K09), while the range for *Halophila* seagrass was between 1.0 (PP-K11) and 3.1 (PB-K09).

5. Results – Temporal trends (Baseline 1 to Baseline 4)

5.1 Seagrass areal extent

5.1.1 La Perouse

The combined total mapped areal extent of all seagrass beds with *P. australis* present ‘*Posidonia / Posidonia mixed*’ (including *Posidonia*, *Posidonia / Halophila*, *Posidonia / Zostera* and *Posidonia mixed* beds) at La Perouse for each of the four Baseline Surveys are presented in Table 12, with areal extents for the remaining seagrass categories combined presented as ‘*Halophila / Zostera*’. Time series comparisons across the baseline monitoring period are presented in Figure 5, with mapped seagrass areal extents presented in Figure 6.

The key results of *P. australis* mapping at La Perouse include the following:

- No *P. australis* has been identified within the Construction Footprint or Buffer Area at La Perouse (Table 12).
- Within the Project Boundary at La Perouse, an overall decline in the area of *P. australis* has occurred between Baseline 1 and Baseline 4, despite a relative increase in Baseline 4 when compared to the Baseline 2 and Baseline 3 surveys (Figure 5).
- Similar trends among surveys appear to have occurred within the Survey Area and within the Project Boundary in the cases of *P. australis* seagrass areas and *Halophila / Zostera* areas (Figure 5).

Table 12: *P. australis* seagrass (including *Posidonia*, *Posidonia / Halophila*, *Posidonia / Zostera* and *Posidonia Mixed* beds) areas and *Halophila / Zostera* areas mapped during Baseline Surveys to date at La Perouse.

Seagrass area (m ²)	Baseline 1	Baseline 2	Baseline 3	Baseline 4
Buffer Area				
Halophila / Zostera	3526	2505	78	51
Posidonia / Posidonia mixed	0	0	0	0
Construction Footprint				
Halophila / Zostera	991	673	0	0
Posidonia / Posidonia mixed	0	0	0	0
Project Boundary				
Halophila / Zostera	27235	24921	9502	9072
Posidonia / Posidonia mixed	170	135	137	159
Survey Area				
Halophila / Zostera	29480	22359	10241	10975
Posidonia / Posidonia mixed	550	431	254	411

For ease of reference, the grid tick marks and labels shown around the border of the map are presented in GDA2020, using the relevant MGA zone.

5.1.2 Kurnell

The combined total mapped areal extent of all seagrass beds with *P. australis* present ‘*Posidonia / Posidonia mixed*’ (including *Posidonia*, *Posidonia / Halophila*, *Posidonia / Zostera* and *Posidonia mixed* beds) at Kurnell for each of the four Baseline Surveys are presented in Table 13, with areal extents for the remaining seagrass categories combined presented as ‘*Halophila / Zostera*’. Time series comparisons across the baseline monitoring period are presented in Figure 7, with mapped seagrass areal extents presented in Figure 8.

The key results of *P. australis* mapping at Kurnell include the following:

- In Baseline 4, a total 258 m² of *P. australis* seagrass was mapped within the Construction Footprint and Buffer Area combined (Table 12, Figure 6), with a total of 7 m² within the Construction Footprint alone.
- There has been an overall decline in the mapped areal extent of *P. australis* within the Construction Footprint during the Baseline Surveys (Figure 7). In contrast, there has been an overall increase in area of *P. australis* within the Buffer Area since Baseline 2. An overall decrease in *P. australis* areal extent has also been detected within the Project Boundary from Baseline 1 to Baseline 4, despite a relative increase between Baseline 1 and Baseline 2.
- In the Survey Area there has been a relatively minor overall increase in *P. australis* seagrass area across the surveys, despite a spike detected in Baseline 2 and subsequent decrease in Baseline 3.
- Similar trends of declining *Halophila / Zostera* areas occurred in the Survey Area and within the Project Boundary, with this decline most acute between Baseline 2 and Baseline 3 (Figure 7). However, a more acute decline in areas of *Halophila / Zostera* appears to have continued from Baseline 3 to Baseline 4 in the Survey Area compared to within the Project Boundary.

Table 13: *P. australis* seagrass (including *Posidonia*, *Posidonia / Halophila*, *Posidonia / Zostera* and *Posidonia Mixed* beds) areas and *Halophila / Zostera* areas mapped during Baseline Surveys at Kurnell to date.

Seagrass area (m ²)	Baseline 1	Baseline 2	Baseline 3	Baseline 4
Buffer Area				
Halophila / Zostera	3975	4365	3597	2835
Posidonia / Posidonia mixed	228	220	263	251
Construction Footprint				
Halophila / Zostera	975	1027	818	733
Posidonia / Posidonia mixed	20	14	5	7
Project Boundary

5.2 *Zostera* and *Halophila* seagrass beds

5.2.1 La Perouse

At La Perouse drop camera monitoring sites there has been a large decrease in *Zostera* and *Halophila* seagrass cover, from between 14% and 24% cover in Baseline 1 down to 7% or less in Baseline 4 (Figure 9). The two-factor univariate PERMANOVA found a significant interaction term ($df=9$, $f=4.75$, $p=0.0001$, Appendix 6), indicating that patterns of differences among surveys were dependent on site, and among sites were dependent on survey. The Pairwise Tests confirmed that significant differences among surveys were between Baseline 1 and all other surveys across all sites, while there were some further significant differences among surveys from Baseline 2 to Baseline 4 for some (e.g., LP04), but not all sites (Appendix 6). That is, *Zostera* and *Halophila* seagrass cover decreased similarly and significantly from Baseline 1 to Baseline 2 for all sites (Figure 9). Those decreases were then sustained from Baseline 2 through to Baseline 4, although some sites exhibited further significant decreases during that time, albeit to a lesser extent than the Baseline 1 to 2 decreases (e.g., LP04).

Another notable observed difference was that *Zostera* and *Halophila* seagrass cover was found to be greater at the sites outside the Project Boundary (HZ-LP03 and HZ-LP04) than those within the Project Boundary (HZ-LP01 and HZ-LP02) during the first two Baseline surveys (Figure 9). This was supported by the general pattern of statistically significant differences detected between pairs of sites during the first two surveys for seagrass cover, as indicated by the paired tests (Appendix 6).

Analysis of the full set of percent cover data via three-factor multivariate PERMANOVA also found a significant interaction term ($df=6$, $f=15.70$, $p=0.0001$, Appendix 6), indicating patterns of differences between surveys (within season) were dependent on site, and among sites were dependent on survey. The PCoA graph shows that while there is some limited overlap of the clusters of data points for Baseline 1 (green) and Baseline 2 (blue), there is clearly a degree of separation overall (Figure 10). In contrast, there is almost no overlap of clustering between Baseline 1 and Baselines 3 (aqua) or 4 (red), which substantially overlap each other. The length and direction of the radiating *Halophila* line matches the direction of disparity of the Baseline 1 cluster, indicating that the difference is primarily being driven by temporal differences in the presence of *Halophila*.

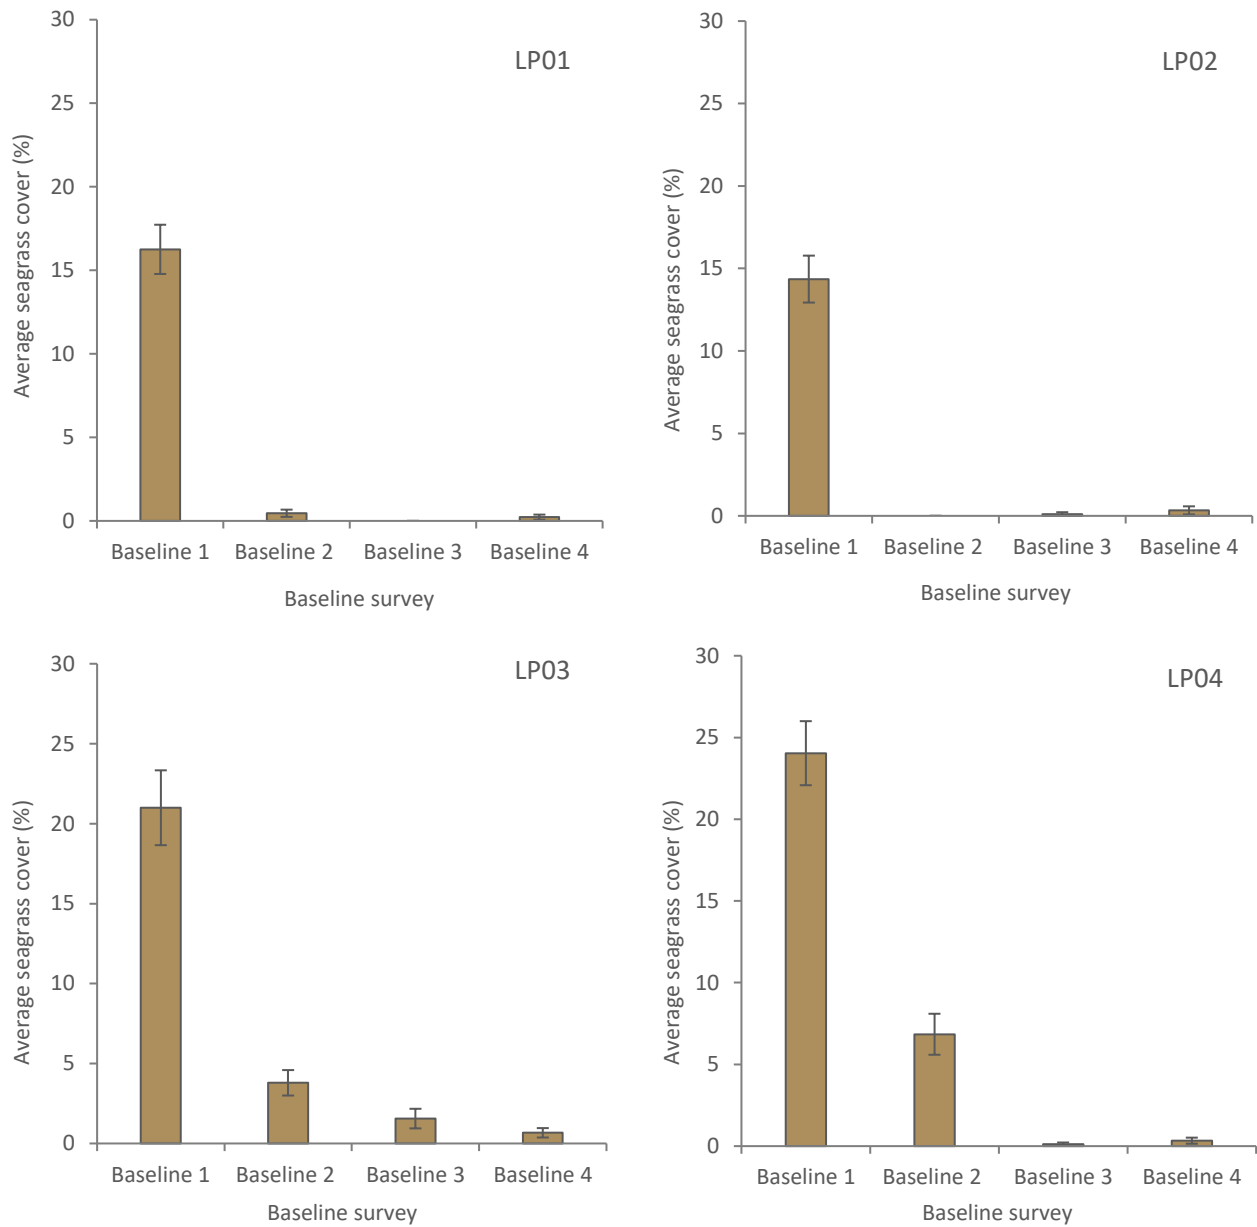

Figure 9: Mean seagrass cover within the *Zostera* and *Halophila* dominated bed sites across the Baseline Surveys at La Perouse.

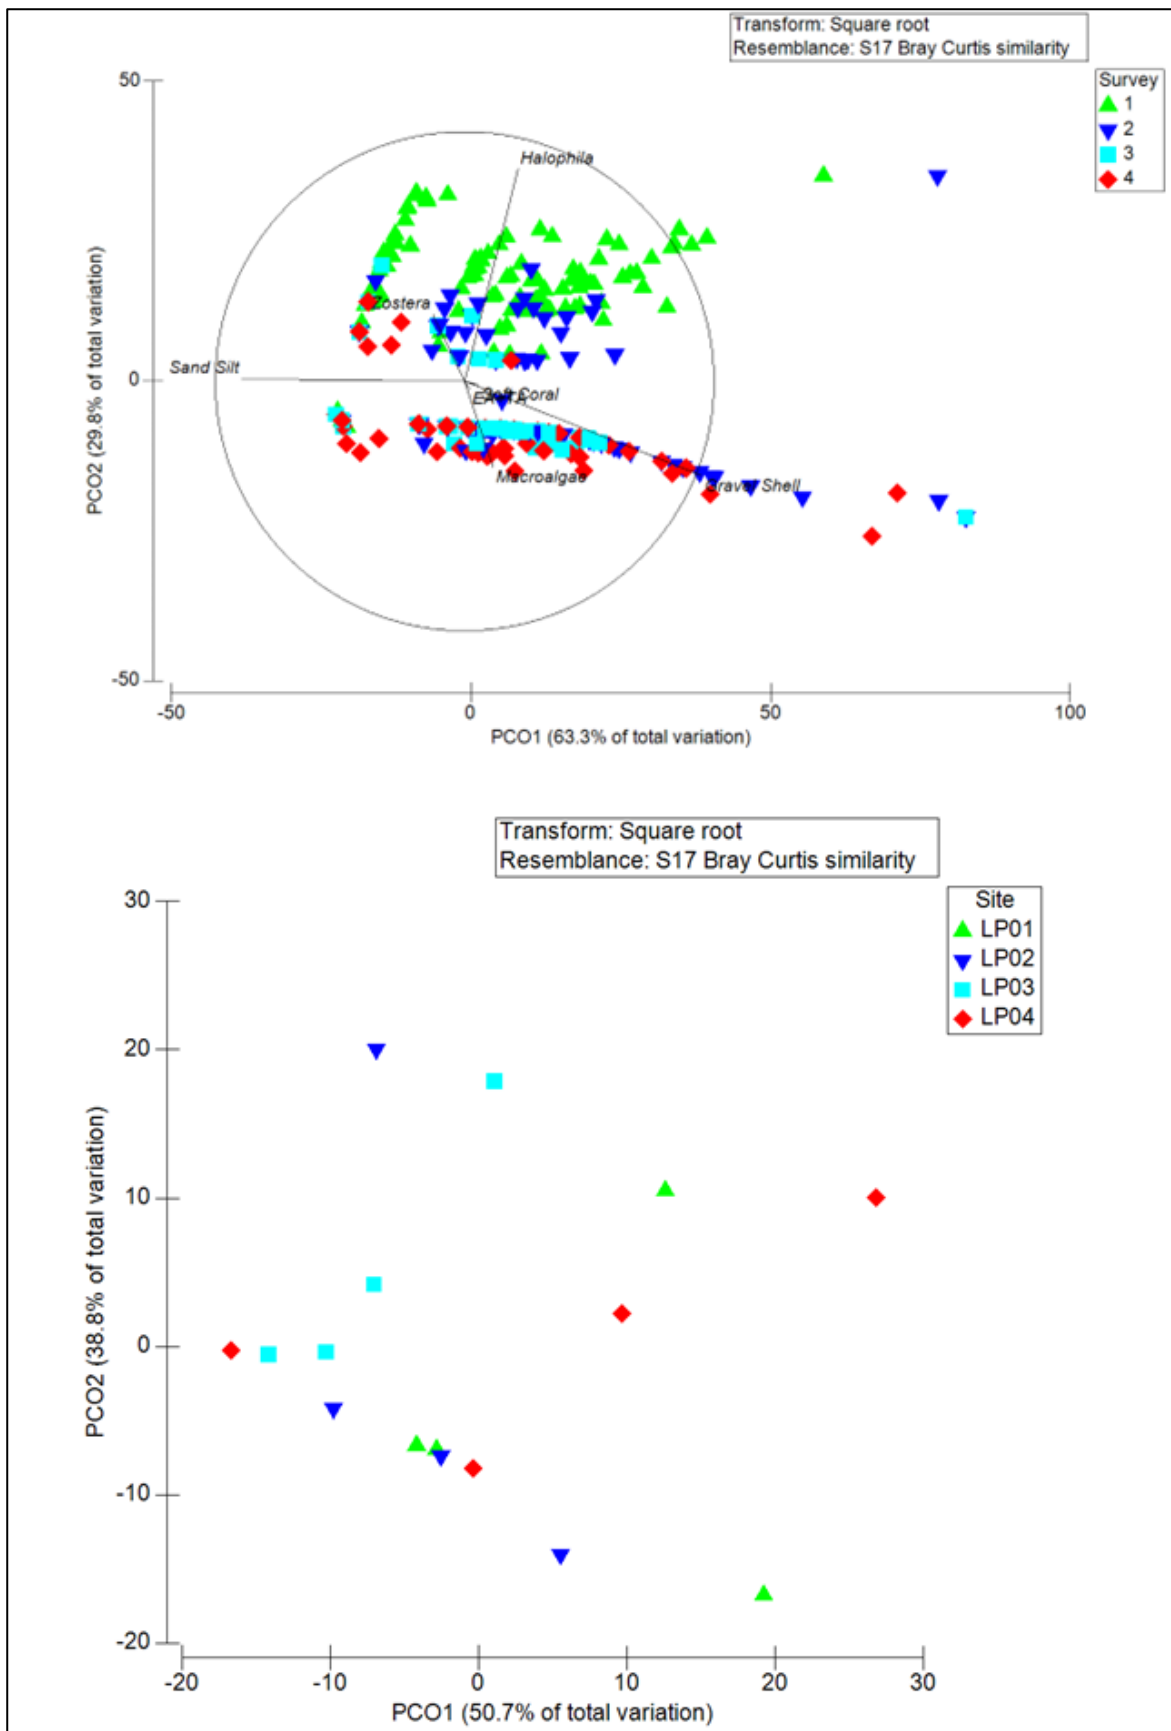

Figure 10: PCoA Graphs for La Perouse. Top: All data displayed by survey. Bottom: Centroids of Site and Survey combined displayed by site.

5.2.2 Kurnell

At Kurnell drop camera monitoring sites the *Zostera* and *Halophila* seagrass cover has been much more variable. At the sites further from shore (HZ-K05 to HZ-K08) cover has remained less than 5%, while two sites close to shore (HZ-K09 and HZ-K10) have displayed much greater change, ranging from cover above 40% to less than 5%. In general, there appears to have been a common pattern of decline in cover between Baseline 1 and 3, then a trend of increase to the most recent survey (Figure 11). As was the case for La Perouse, the statistical analysis detected a significant interaction term ($df=15$, $f=39.85$, $p=0.0001$, Appendix 6), indicating that patterns of differences among surveys were dependent on site, and among sites were dependent on survey. The Pairwise Tests confirmed that these differences were typically between Baseline 3 and other surveys, with the exception of HZ-K06 where no significant differences between surveys were detected (Appendix 6).

In general, seagrass cover was found to be greater at the shallower sites closer to shore (HZ-K09 and HZ-K10) than those further from shore (Figure 11). Statistically significant differences were also detected among sites for seagrass cover and the full set of percent cover data in the cases of each of the four surveys (Appendix 6).

Analysis of the full set of percent cover data via three-factor multivariate PERMANOVA resulted in a similar finding ($df=10$, $f=28.895$, $p=0.0001$, Appendix 6), with patterns of differences among surveys dependent on site, and among sites dependent on survey. The PCoA graph indicates that the most recent survey (Baseline 4) was much more variable than earlier surveys, with both *Zostera* and *Halophila* having a strong negative relationship with the X Axis (Figure 12).

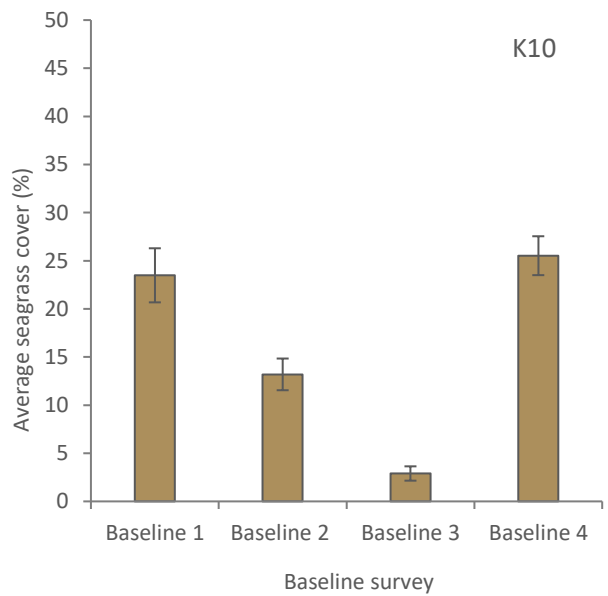

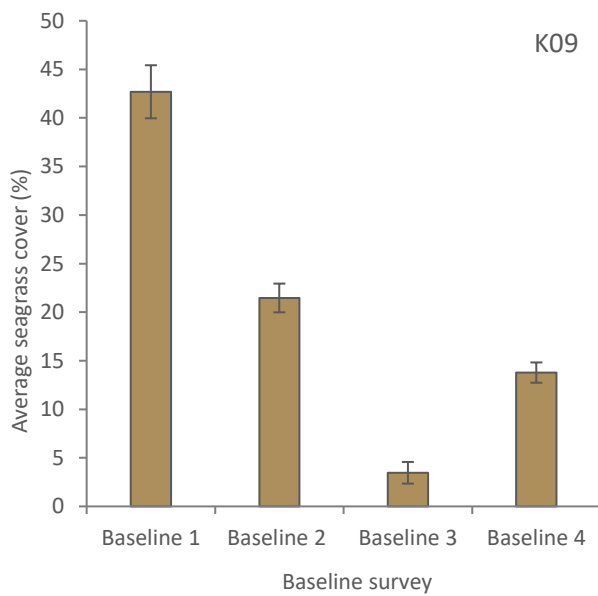

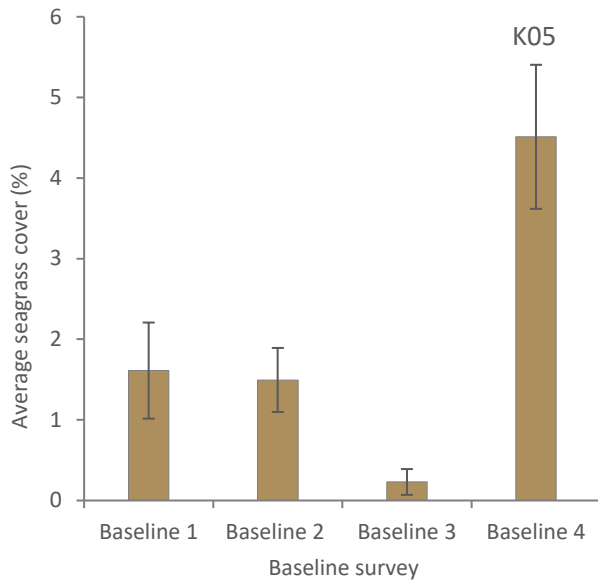

Figure 11: Mean seagrass cover within the *Zostera* and *Halophila* dominated bed sites across the Baseline Survey at Kurnell.

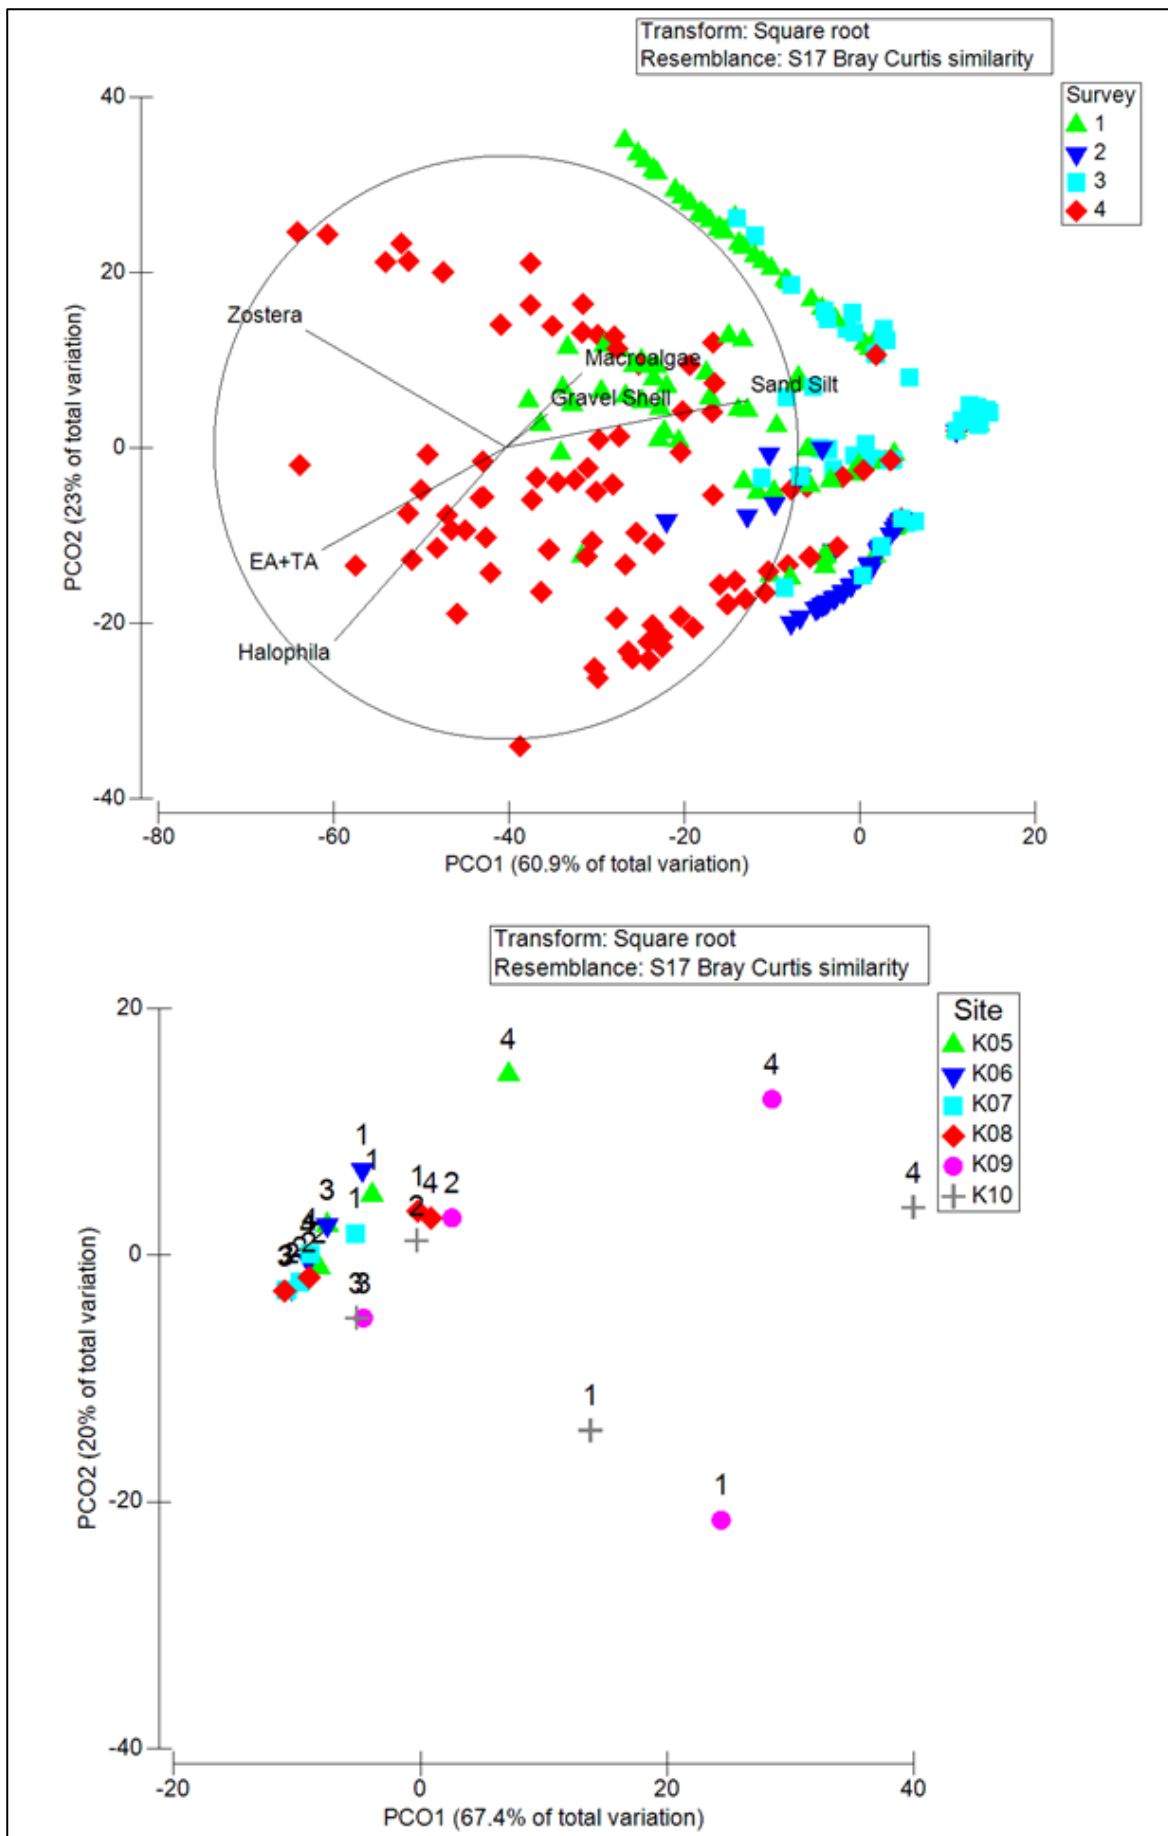

Figure 12: PCoA Graphs for Kurnell. Top: All data displayed by survey. Bottom: Centroids of Site and Survey combined displayed by site.

5.3 *Posidonia* bed monitoring

5.3.1 La Perouse

Posidonia Shoots

Posidonia shoot density within the *Posidonia* Bed monitoring sites at La Perouse was generally higher for the first two Baseline Surveys than later surveys, and at site PB-LP12 than at PB-LP11 (Figure 13). The statistical analysis detected significant differences for the Survey (df=3, f=41.48, p=0.0092) and Site (df=1, f=24.35, p=0.0257) main effects terms, indicating differences across the four surveys irrespective of site, and differences between the two sites irrespective of survey (Appendix 6). Subsequent Pairwise Tests determined that the significant temporal difference detected was driven by a general decrease in shoot density from Baseline 1 in comparison with Baseline 4 at both sites (i.e., B1=B2>B3>B4, Appendix 6).

Figure 13: Mean shoot density of *Posidonia* shoots at the La Perouse *Posidonia* bed monitoring sites. Top: Between surveys. Bottom: Between sites.

***Posidonia* Leaf Length**

At La Perouse, leaf lengths at PB-LP11 notably decreased from the first two Baseline surveys (which were generally similar) to the last two Baseline Surveys (also generally similar), while leaf lengths at PB-LP12 were generally more variable across the four surveys (Figure 14). The statistical analysis detected a significant interaction ($df=3$, $f=7.73$, $p=0.0005$, Appendix 6), indicating that patterns of differences among surveys were dependent on site, and between sites were dependent on survey. The Pairwise Tests showed that at PB-LP11 leaf lengths were significantly different among all surveys, while at PB-LP12 leaf lengths were significantly shorter for the Baseline 3 survey than for all other surveys (Appendix 6).

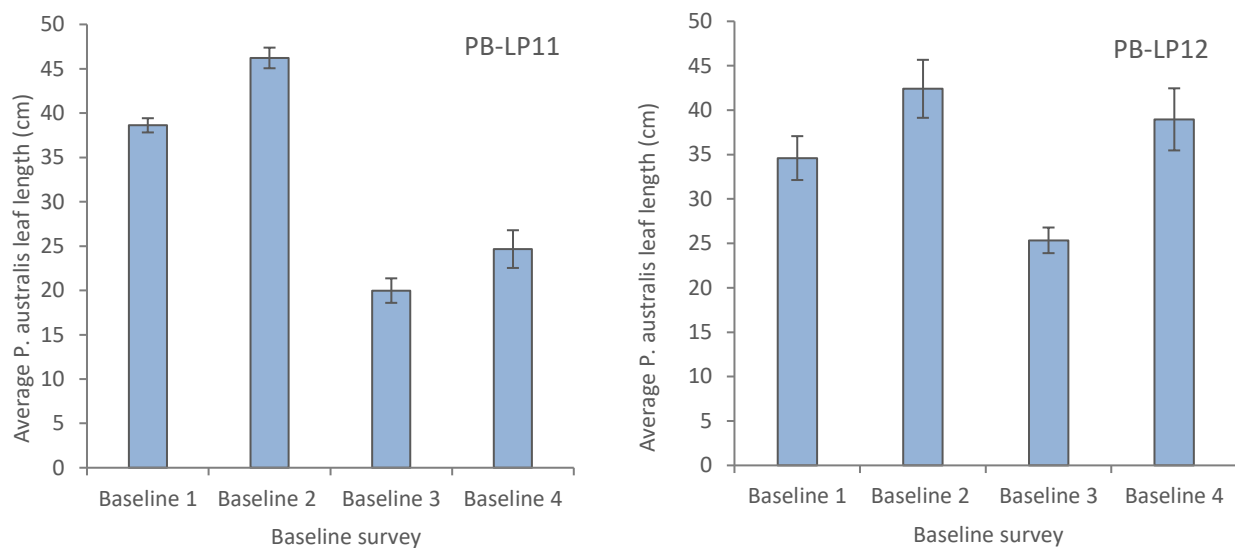

Figure 14: Mean leaf length of *Posidonia* at the La Perouse *Posidonia* bed monitoring sites.

***Posidonia* epiphytes**

At La Perouse, epiphyte load scores indicated moderate to high epiphyte cover across all Baseline Surveys (Figure 15), with scores at PB-LP12 higher and more variable for winter surveys (Baseline 1 and 3) than for summer surveys (Baseline 2 and 4) (Figure 16). The three-factor PERMANOVA detected a significant interaction for Season x Site ($df=1$, $f=27.44$, $p=0.0002$, Appendix 6), indicating that patterns of differences between seasons were dependent on site, and between sites were dependent on seasons, while a significant difference between Surveys (within Seasons) was also detected ($df=2$, $f=6.57$, $p=0.0038$, Appendix 6). The Pairwise Tests did not detect any significant differences between Seasons for either Site, only between Sites within the Winter Season but not Summer (Appendix 6). Pairwise tests also detected a significant difference between the two Winter Surveys irrespective of Site, but not for the Summer Surveys.

Figure 15: Mean epiphyte load scores of *Posidonia* at the La Perouse *Posidonia* bed monitoring sites between surveys.

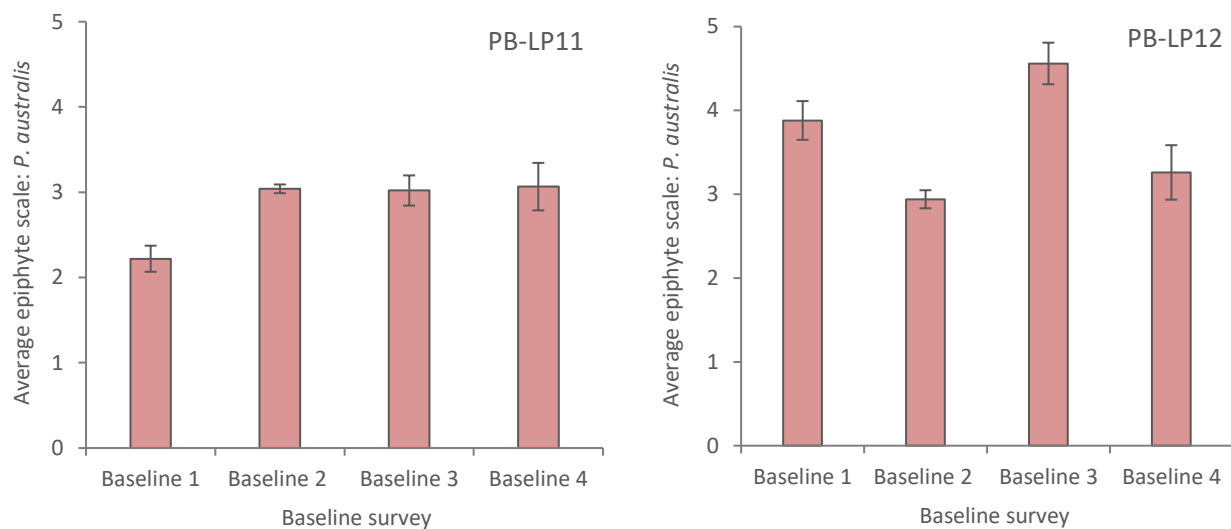

Figure 16: Mean epiphyte load scores of *Posidonia* at the La Perouse *Posidonia* bed monitoring sites.

***Posidonia* Bed composition**

The *Posidonia* beds at La Perouse consisted primarily of *Posidonia*, with the level of presence of *Zostera* and *Halophila* amongst the *Posidonia* being much more variable (Figure 6, Appendix 4). Multivariate analysis of the data detected a significant interaction ($df=3$, $f=5.19$, $p=0.0007$, Appendix 6), indicating that patterns of differences among surveys were dependent on site, and between sites were dependent on survey. Pairwise Tests indicated that bed composition at PL-LP11 significantly differed among most surveys, with the exception being Baseline 3 and Baseline 4 surveys, which did not significantly differ from each other (Appendix 6). In contrast, bed composition at PB-LP12 was found to be significantly different only for the Baseline 4 vs Baseline 1 and Baseline 4 vs Baseline 2 comparisons. Significant differences between sites were also detected for Surveys 1, 3 and 4 (Appendix 6).

The PCoA graph indicates that lower *Zostera* and *Halophila* shoot counts in Baseline 3 and Baseline 4 were a major driver of differences in seagrass bed composition within the La Perouse *Posidonia* Bed monitoring sites. Differences in seagrass composition between sites is illustrated by the PCoA of the Centroid data, which shows PB-LP11 to be much more variable (Figure 17).

Figure 17: PCoA Graphs for seagrass composition at La Perouse *Posidonia* Bed monitoring sites. Top: All data displayed by survey. Bottom: Centroids of Site and Survey combined displayed by Site.

5.3.2 Kurnell

Posidonia shoots

Posidonia shoot density within the *Posidonia* Bed monitoring sites at Kurnell was variable among Baseline surveys and among sites (Figure 18). The statistical analysis detected a significant interaction ($df=27$, $f=12.96$, $p=0.0001$, Appendix 6), indicating that patterns of differences among surveys were dependent on site, and between sites were dependent on survey. Pairwise Tests determined that the patterns of significant differences among surveys varied by site, and vice versa (Appendix 6).

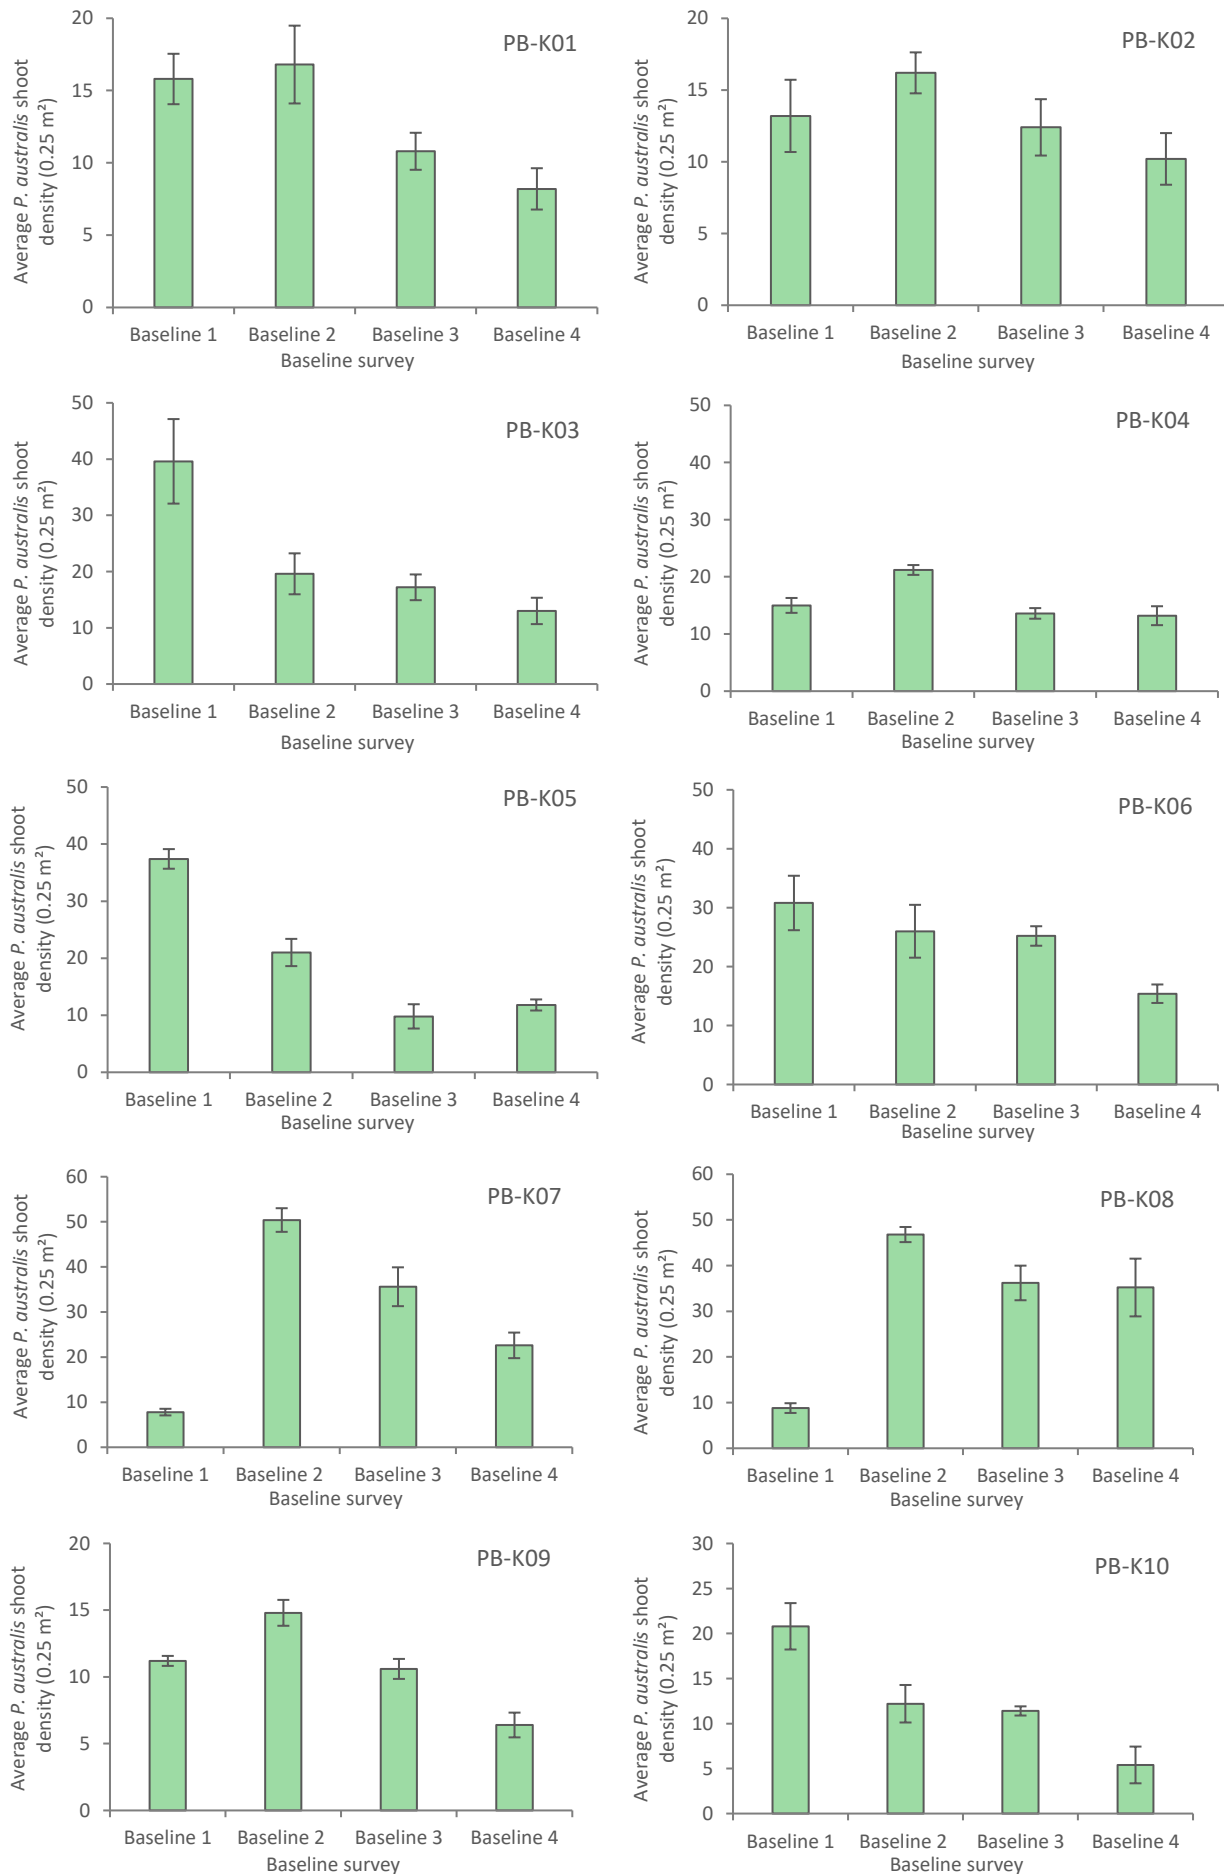

Figure 18: Mean shoot density of *Posidonia* shoots at the Kurnell *Posidonia* bed monitoring sites.

Significant linear regression relationships between shoot density (response variable) and distance from the proposed Construction Footprint (independent variable) were detected for the Inner Transect across all Baseline surveys, while no significant linear relationships were detected at all for the Outer Transect (Figure 19, Appendix 6). For the mostly positive linear relationships detected for the Inner Transect, the coefficient of determination measure of goodness-of-fit (i.e., R-squared) was of moderate strength (< 0.5) for the first two surveys (but note that shoot density was found to have a negative relationship with distance in Baseline 1), and weak (0.4-0.5) in the last two surveys. However, the relationship between distance and the combined data was very weak (<0.1), likely due to the negative linear relationship that occurred for Baseline 1 (Appendix 6).

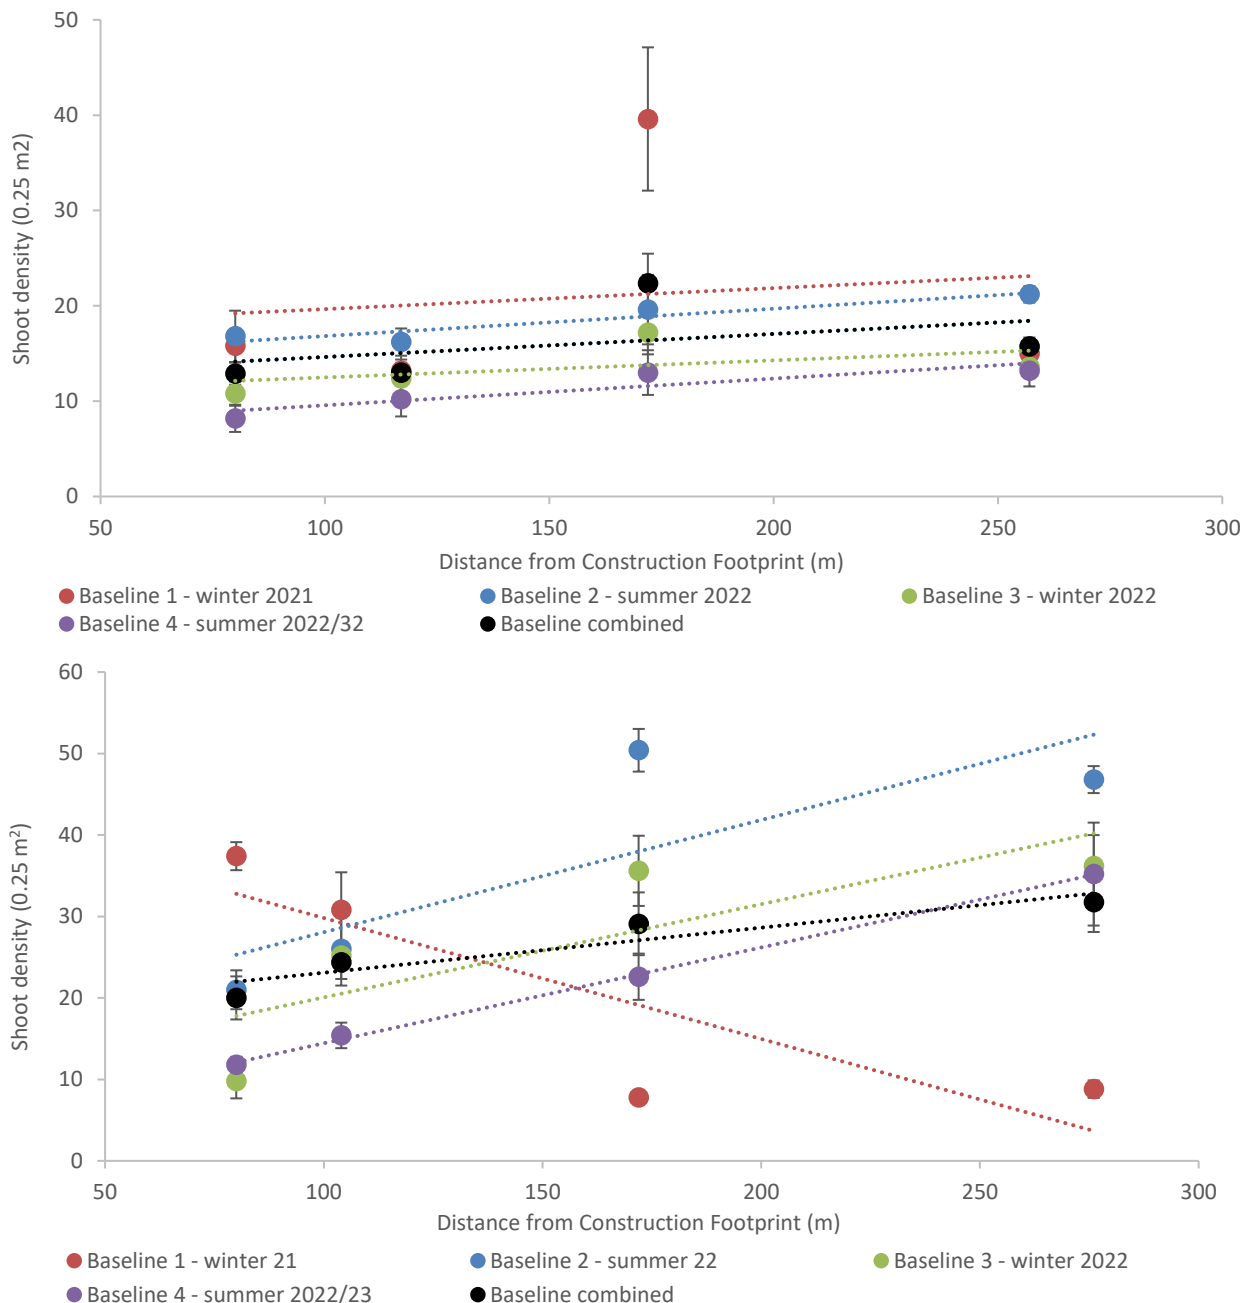

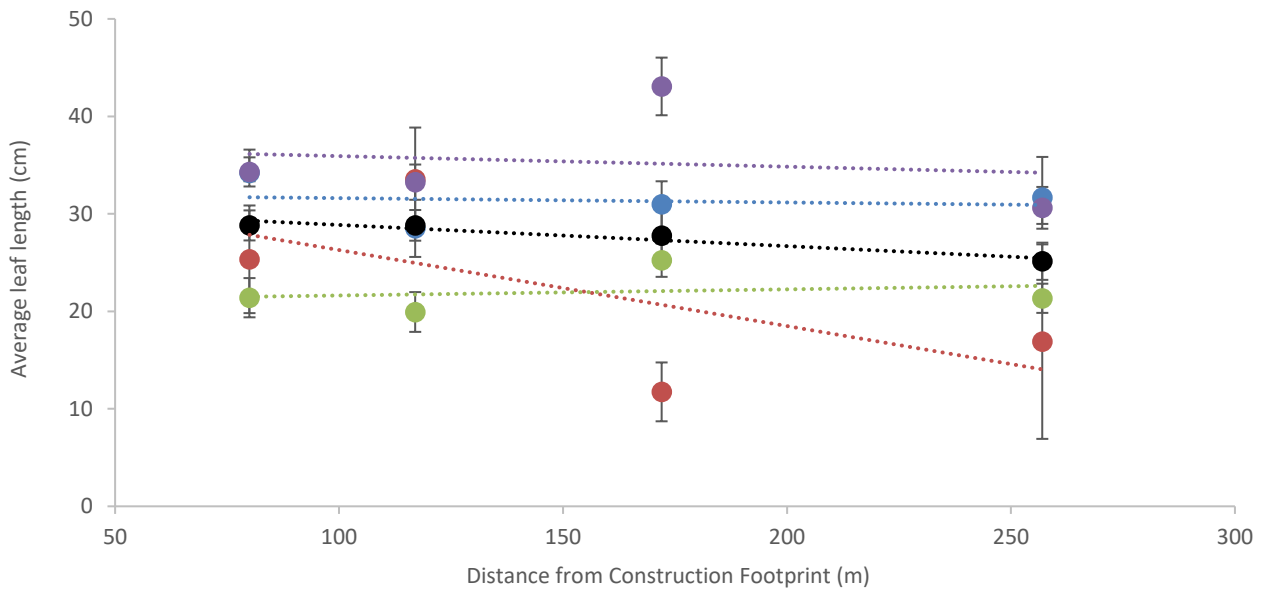

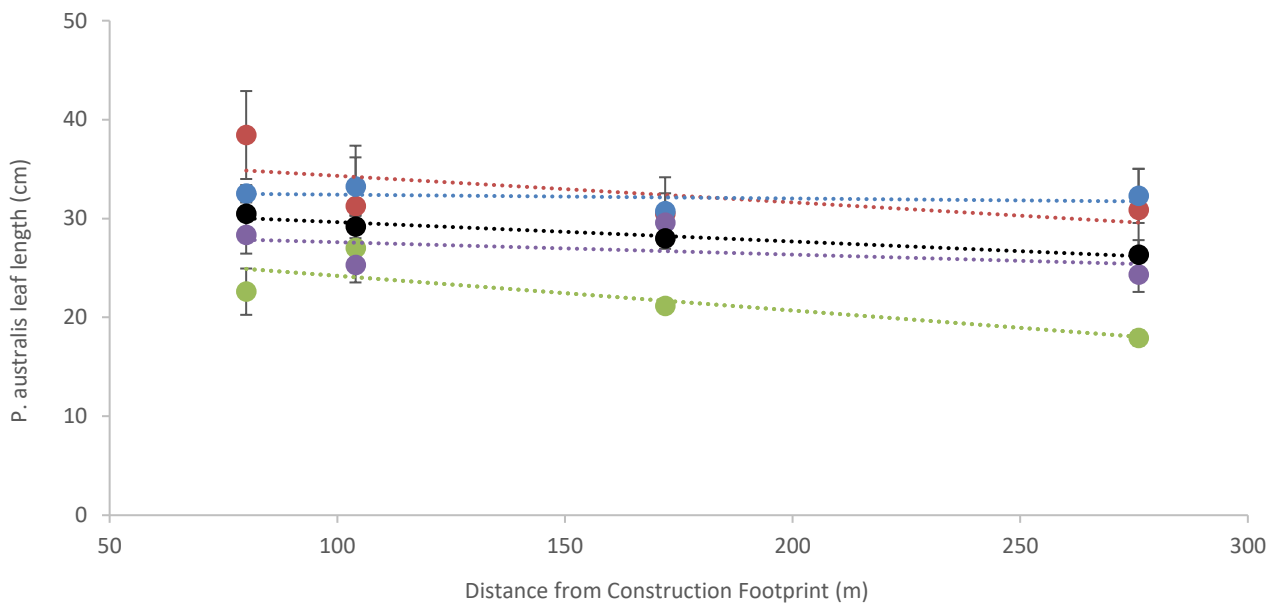

Figure 19: Relationship between *Posidonia* shoot density and distance from the Construction Footprint at Kurnell *Posidonia* bed monitoring sites, Outer Transect (Top), Inner Transect (Bottom). Indicative line-of-best-fit is shown for each Baseline survey and for all surveys combined, irrespective of whether the regression analysis was statistically significant or not.

● Baseline 1 - winter 21 ● Baseline 2 - summer 22 ● Baseline 3 - winter 22 ● Baseline 4 - summer 22/23 ● Baseline combined

Figure 20: Relationship between *Posidonia* Leaf length and distance from the Construction Footprint at Kurnell *Posidonia* bed monitoring sites, Outer Transect (Top), Inner Transect (Bottom). Indicative line-of-best-fit is shown for each Baseline survey and for all surveys combined, irrespective of whether the regression analysis was statistically significant or not.

***Posidonia* leaf length**

At Kurnell, *Posidonia* leaf lengths were variable among surveys and among sites, however a pattern of reduced leaf length in Baseline 3 in comparison to Baseline 2 and Baseline 4 was evident across almost all sites, with the exception being PB-K06 (Figure 21). The three-factor PERMANOVA detected a significant interaction ($df=18, f=7.76, p=0.0001$, Appendix 6), indicating that patterns of differences between surveys (within seasons) were dependent on site, and among sites were dependent on survey. Pairwise Tests found that leaf length for surveys within both the Winter season (Baselines 1 and 3) and Summer season (Baselines 2 and 4) were significantly different from each other at some sites (Appendix 6).

A significant negative linear regression relationship between leaf length (response variable) and distance from the proposed Construction Footprint (independent variable) was detected for the Outer Transect only for Baseline 1, with analyses for the other three surveys and the combined data not indicating any significant relationships (Figure 20, Appendix 6). A similar result, but with Baseline 3 having the significant negative linear relationship, was evident for the Inner Transect. The coefficient of determination measure of goodness-of-fit (i.e., R-squared) was of weak strength for the Outer Transect in Baseline 1 and Inner Transect in Baseline 3 (<0.4) (Appendix 6).

***Posidonia* Epiphytes**

At Kurnell the epiphyte load scores indicated moderate to high epiphyte cover across all surveys (Figure 22). The statistical analysis detected a significant interaction ($df=27$, $f=6.69$, $p=0.0001$, Appendix 6), indicating that patterns of differences among surveys were dependent on site, and among sites were dependent on survey. Pairwise Tests determined that there were significant differences among surveys for almost all sites, with the exceptions being PB-K02 and PB-K09, while significant differences occurred among some pairs of sites for most Surveys, with the exception being Baseline 3 (Appendix 6).

***Posidonia* bed composition**

The *Posidonia* beds at Kurnell consisted primarily of *Posidonia*, with *Zostera* and *Halophila* also present, albeit much more variably so (Figure 8, Appendix 4). Multivariate analysis of the data detected a significant interaction ($df=27$, $f=5.47$, $p=0.0001$, Appendix 6), indicating that patterns of differences among surveys were dependent on site, and among sites were dependent on survey. The Pairwise Tests detected significant differences among surveys at all sites, and vice versa (Appendix 6).

The PCoA graph indicates that higher *Zostera* and *Halophila* shoot counts (especially *Halophila* in Baseline 2) were the major drivers of temporal differences in seagrass composition within Kurnell *Posidonia* Bed monitoring sites. Differences in seagrass composition among sites is illustrated by the PCoA of the Centroid data, which shows sites PB-K01 to PB-K05 to typically be less variable than Sites PB-K06 to PB-K10 (Figure 23).

5.4 *Posidonia* patches

5.4.1 La Perouse

PP-LP01

PP-LP01 is a patch of *Posidonia* approximately 25 metres to the east of the Construction Footprint.

An overall decline in *Posidonia* patch size has occurred between Baseline 1 and Baseline 4. The greatest decline occurred between Baseline 1 and Baseline 2. While patch size increased from Baseline 2 to Baseline 3, a minor decline then occurred between Baseline 3 and Baseline 4 (Figure 24).

There was a trend of decreasing *Posidonia* shoot counts from Baseline 2 to Baseline 4 within this patch (Figure 25). This was supported by the detection of a significant difference among surveys ($df=3$, $f=5.59$, $p=0.0223$). Subsequent pairwise tests then found significant differences between Baseline 4 and Baseline 1, and between Baseline 4 and Baseline 2, while all other pairs of surveys did not significantly differ (Appendix 6).

PP-LP02

PP-LP02 is a patch of *Posidonia* approximately 40 metres to the east of the Construction Footprint.

There has been a trending decline in *Posidonia* patch size between Baseline 1 and Baseline 4, with the greatest decline occurring between Baseline 1 and Baseline 2 (Figure 24).

Posidonia shoot counts at this site have remained relatively similar across most surveys, at 10-15 shoots per 0.25m^2 , with the exception being Baseline 2, where counts were over 20 shoots per 0.25m^2 (Figure 25). This was supported by the detection of a significant difference among surveys ($df=3$, $f=4.73$, $p=0.0198$). Pairwise tests found that shoot counts for Baseline 2 were significantly higher than for all other surveys (Appendix 6).

Figure 24: *Posidonia* patch size at the La Perouse *Posidonia* patch monitoring sites

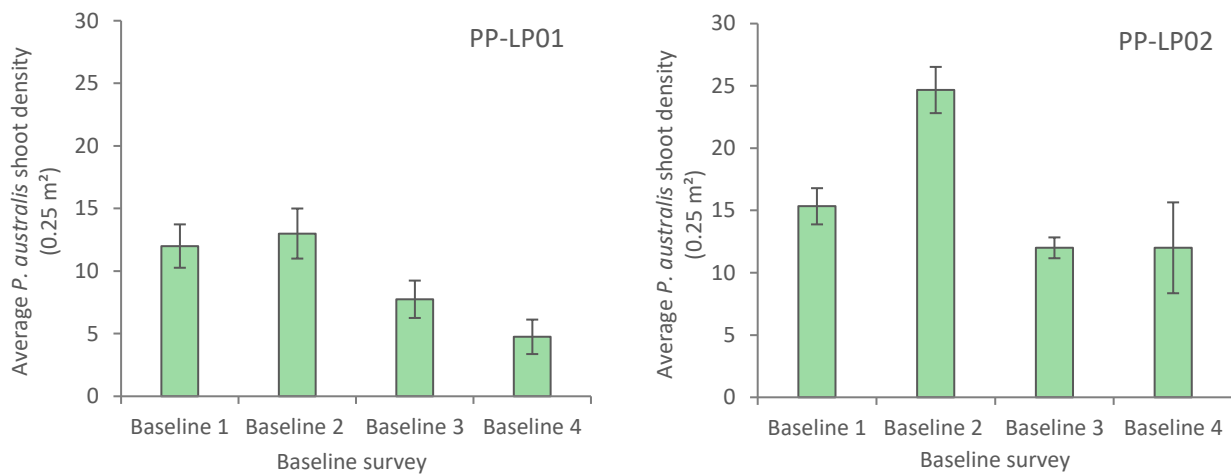

Figure 25: Mean *Posidonia* shoots at the La Perouse *Posidonia* patch monitoring sites.

5.4.2 Kurnell

PP-K03

PP-K03 is a patch of *Posidonia* approximately 30 metres to the east of the Construction Footprint.

Posidonia patch size at PP-K03 has been relatively stable across the four Baseline surveys. A small trending increase occurred between Baseline 1 and Baseline 3, before a decline to Baseline 4 (Figure 26).

There was a trend of decreasing *Posidonia* shoot counts from Baseline 1 to Baseline 3 within this patch (Figure 27). This was supported by the detection of a significant difference between surveys ($df=3$, $f=13.78$, $p=0.0006$). Pairwise tests found that this difference was due to shoot counts being significantly higher for Baseline 1 than all other surveys, and significantly higher for Baseline 2 than Baselines 3 and 4 (Appendix 6).

PP-K04

PP-K04 is a patch of *Posidonia* that extends from the eastern side of the Construction Footprint.

Posidonia patch size at PP-K04 has been relatively stable across the four Baseline surveys. A small trending increase occurred between Baseline 1 and Baseline 3, before declining in Baseline 4 (Figure 26).

Posidonia shoot counts were similar across all surveys, ranging between 10-14 shoots per 0.25 m² (Figure 27). This was supported by the statistical analysis, which did not detect any significant difference among surveys ($df=3$, $f=0.91$, $p=0.465$ Appendix 6).

PP-K07

PP-K07 is a patch of *Posidonia* approximately 10 metres to the west of the Construction Footprint.

Posidonia patch size at PP-K07 declined substantially between Baseline 1 and Baseline 2. A small increase then occurred between Baseline 2 and Baseline 3, before a decline to Baseline 4 (Figure 26).

Posidonia shoot counts were typically between 5-10 shoots per 0.25 m² for each survey, with the exception being a higher shoot density in Survey 2 (Figure 27). However, the statistical analysis did not detect any significant difference among surveys ($df=3$, $f=2.86$, $p=0.059$ Appendix 6).

PP-K08

PP-K08 is a patch of *Posidonia* adjacent to the western edge of the Construction Footprint.

Posidonia patch size at PP-K08 declined substantially between Baseline 1 and Baseline 2. A small increase then occurred between Baseline 2 and Baseline 3, before a decline to Baseline 4 (Figure 26).

Posidonia shoot counts for the most recent two surveys (Baseline 3 and Baseline 4) were similar, but substantially lower than counts for Baseline 1 and Baseline 2, which were also similar (Figure 27). This was supported by the detection of a significant difference among surveys (df=3, f=12.46, p=0.0008). Pairwise tests collectively indicated that the decrease in shoot counts from Baseline 2 to Baseline 3 was significant (Appendix 6).

PP-K09

PP-K09 is a patch of *Posidonia* adjacent to the eastern edge of the Construction Footprint.

Posidonia patch size at PP-K09 declined substantially between Baseline 1 and Baseline 2. A small increase then occurred between Baseline 2 and Baseline 3, before a decline to Baseline 4 (Figure 26).

Posidonia shoot counts were typically similar, ranging between 10-15 shoots per 0.25 m² across surveys (Figure 27). This was supported by the statistical analysis, which did not detect any significant difference among surveys (df=3, f=1.11, p=0.3487 Appendix 6).

PP-K11

PP-K11 is a patch of *Posidonia* approximately 5 metres to the east of the Construction Footprint.

Posidonia patch size at PP-K11 declined substantially between Baseline 1 and Baseline 2. A small increase then occurred between Baseline 2 and Baseline 3, before a decline to Baseline 4 (Figure 26).

Posidonia shoot counts were typically very similar (approx. 15 shoots per 0.25 m²) across the first three surveys, although there was a notable decline in shoot density from Baseline 3 to Baseline 4 (Figure 27). The statistical analysis did not detect any significant difference between Surveys (df=3, f=1.11, p=0.3487 Appendix 6), indicating that declines observed in the most recent survey were not statistically significant.

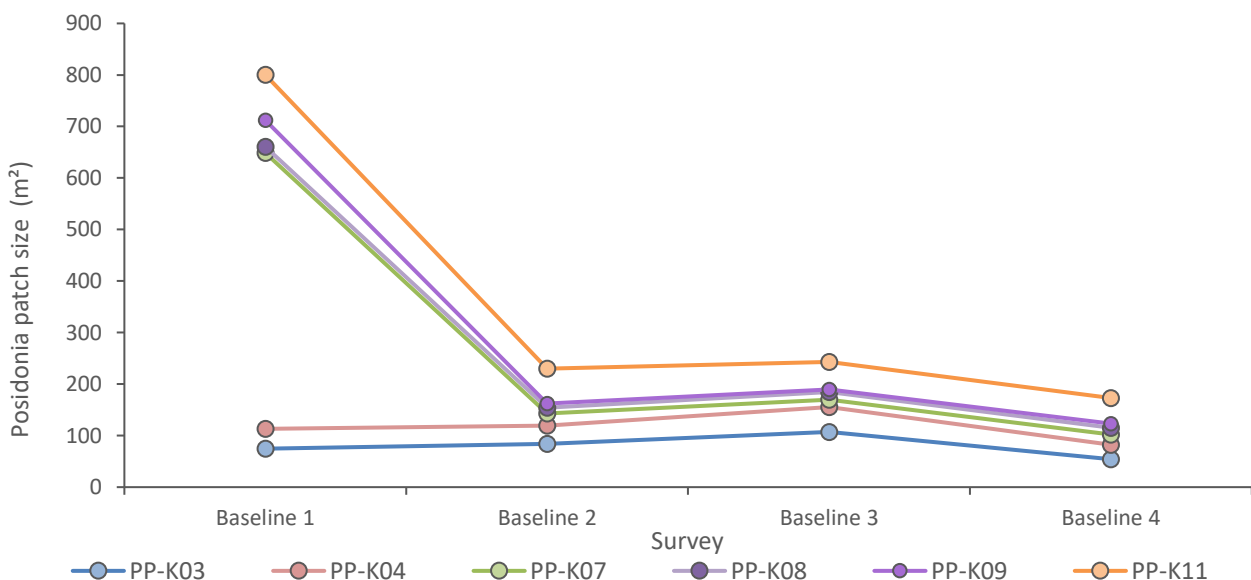

Figure 26: *Posidonia* patch size at the Kurnell *Posidonia* patch monitoring sites

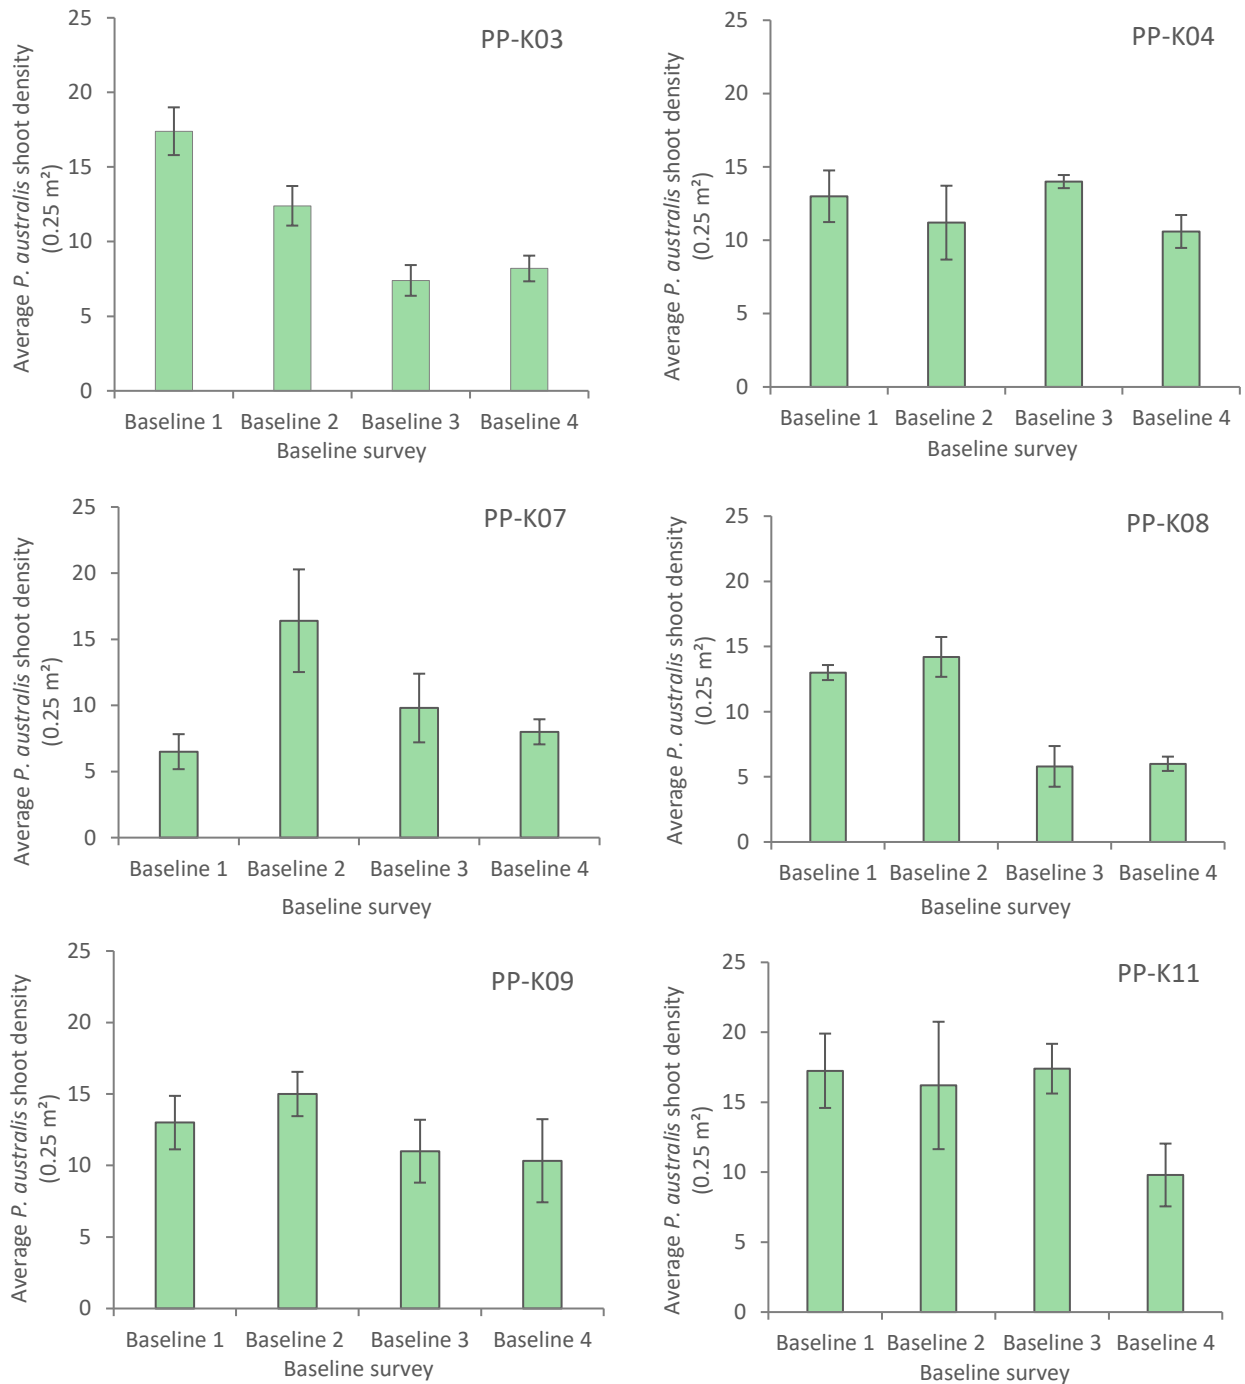

Figure 27: Mean *Posidonia* shoots at the Kurnell *Posidonia* patch monitoring sites.

6. Discussion

6.1 Summary of baseline findings

6.1.1 Seagrass areal extent

Seagrasses within the Project Boundaries at both La Perouse and Kurnell are dominated by *Halophila* and *Zostera* beds, which have typically declined in areal extent since the start of Baseline Surveys. *Posidonia* seagrass beds have a much lesser contribution to areal extent of seagrasses within both Project Boundaries, although the areal extent and extent of *Posidonia* remained relatively stable across the Baseline Surveys.

At La Perouse only 51 m² of seagrass (all *Halophila/Zostera*) was present by the end of the Baseline Surveys – all confined to the Buffer Area and expected to be impacted by the Project. This represented approximately 1% of the total areal extent of seagrass mapped in this area by the end of Baseline 1. Notably, the magnitude of declines in seagrasses at La Perouse were not as large in the wider Survey Area, with declines since Baseline 1 of approximately 33%. Mapping indicates these declines were the greatest in the nearer-to-shore areas associated with the rock platform and Frenchmans Beach.

Declines in seagrass cover were generally not as great at Kurnell, with seagrass area inside the Construction Footprint and Buffer Area peaking during the Baseline 2 Survey at 5,626 m², and reducing to 3,826 m² by the end of the Baseline Surveys (i.e., a decrease of around 32%). This included 258 m² of *Posidonia* within the Construction Footprint and Buffer Area in Baseline 4, which represents a small overall trend of increase from the 248 m² recorded in Baseline 1. These patterns in seagrass areal extent change were similar in the wider Project Boundary and Study Area at Kurnell, although declines (resulting from a reduction in *Halophila / Zostera*) appeared to be marginally greater in those areas.

6.1.2 *Halophila / Zostera* seagrasses

Monitoring of the *Halophila / Zostera* seagrass beds found that the seagrass beds at both La Perouse and Kurnell were characterised by, in most instances throughout the Baseline surveys, very low seagrass cover (less than 5%), with these levels of cover also highly variable through time. These seagrass beds changed substantially through time irrespective of season at both La Perouse and Kurnell, while spatial variability was also highly evident, especially with respect to differences according to proximity to the shoreline.

At La Perouse, seagrass cover was substantially greater in Baseline 1 than in the other Baseline surveys, with some sites having up to 25% cover in the former survey. By Baseline 4 substantial decreases from Baseline 1 became evident with, for example, levels below 1% cover at monitoring sites adjacent to the Construction Footprint and 5% at potential reference sites. This indicates a clear general decline in *Halophila / Zostera* cover at La Perouse since the commencement of the Baseline Surveys. Interestingly, seagrass cover estimates at the reference sites, which are further from shore, were typically greater but similarly variable.

At Kurnell, the variability in seagrass cover among the *Halophila / Zostera* seagrass beds was much greater than at La Perouse, with temporal trends across the Baseline Surveys less evident. In spatial terms, the original sites located nearer to the shore, including the potential impact and reference sites, appeared very different to the additional near-to-shore sites added in Baseline 1 following the establishment of much denser seagrass bed. Those original sites recorded lower levels of variability and seagrass cover. The additional sites were found to be much more variable and, with the exception of Baseline 3, supported *Halophila / Zostera* seagrass cover of greater than 10%.

6.1.3 *Posidonia* seagrass

Across the Baseline Surveys there was a general trend of decreasing *Posidonia* shoot density within the *Posidonia* beds and patches over time at both locations. These reductions were not consistent across all monitoring sites, indicating that the drivers of any decrease in shoot density were not acting on the *Posidonia* beds and patches equally across the two Survey Areas. The *Posidonia* seagrass beds and patches at both La Perouse and Kurnell typically consist of mixed seagrasses. *P. australis*, the canopy forming species, typically had leaf lengths in excess of 20 cm. *Halophila* and/or *Zostera* occupied the lower stratum and were typically much more variable in occurrence and density.

At La Perouse the *Posidonia* beds declined in shoot density from 100-120 *Posidonia* shoots per m² in the first year of monitoring to 40-60 shoots per m² in the second year. Shoot density was also typically higher at the reference site. Declines in *Posidonia* shoot density were also notable amongst the smaller patches, which may be more vulnerable to edge effects and overall declines in patch size found amongst the patches of *Posidonia* monitored at La Perouse.

Posidonia seagrass at Kurnell included the main bed that commences near to the Project Boundary to the west and various scattered smaller beds and patches that occur across and beyond the Project Boundary to the east. In the main bed, *Posidonia* shoot density was higher (up to 200 shoots per m²) in shallower areas, typically increasing with distance from the Construction Footprint. In the two monitoring sites amongst the smaller beds and patches to the east, *Posidonia* shoot density was typically lower and more variable, at 20-120 shoots per m². Declines in *Posidonia* shoot density across Baseline Surveys were also evident at some monitoring sites, especially those nearer to the edge of the main bed and those amongst beds to the east, as well as some of the patches. Furthermore, detailed observations of individual patch size during the dive surveys at Kurnell indicated that a decline in *Posidonia* areal extent and extent through time at much smaller scales undetected by mapping occurred amongst smaller patches of *Posidonia* within the Project Boundary after Baseline 1.

6.2 Drivers of change

There are a number of potential drivers of change in seagrass areal extent, extent and morphology, including reproductive capacity, environmental conditions, natural environmental disturbances and direct human disturbances that act on seagrasses in Botany Bay. Historical review of aerial imagery since the 1930s has attributed major changes in seagrass areal extent to various stressors that have included oyster shell dredging, release of pollutants, catchment inputs, changes in sedimentary conditions and processes, and large storm events (Larkum and West 1990). These various stressors have resulted in not only seagrass loss but also community composition change, with faster colonising and growing *Zostera* seagrasses typically displacing the slower colonising and growing *P. australis* (Larkum and West 1990), with more recent research indicating the rate of annual change in *P. australis* in Botany Bay is as high as -2.5% (West and Glasby 2021).

Seagrasses can exhibit both asexual and sexual reproduction. Asexual reproduction typically includes the spread of underground rhizomes and roots that produce new shoots (Waycott et al. 2014), while on occasions this may also include dispersal of broken-away fragments that establish in new locations (McMahon et al. 2014). Sexual reproduction, like all plants, includes flowering, pollination, setting and germinating of seeds (Waycott et al. 2014), with many seagrasses having the ability to lay dormant in the sediments until optimal environmental conditions occur (Orth et al. 2000). In Botany Bay, *P. australis* is believed to be typically reliant on asexual reproduction so, given the slow rates of rhizome growth for this species (Larkum and West 1990), any increases in areal extent may take years to detect. In comparison, species of *Halophila* and *Zostera* in Botany Bay may at times display much more rapid growth rates and cyclic changes, taking advantage of seed dormancy. The seeds of *Halophila* and *Zostera* seagrasses may lie dormant for up to 24 and 12 months

respectively (Orth et al. 2000), with the latter typically being negatively buoyant, limiting dispersal to close proximities (approx. 10 m) but allowing for rapid settlement into the sediment for later germination when environmental conditions allow (Smith et al 2014). Rapid increases in *Halophila* and *Zostera* seagrass establishment and areal extent were apparent at times during the Baseline Surveys, especially during Baseline 1 in shallower areas fringing the shoreline at Kurnell. While not detected in the EIS surveys (TfNSW 2021a), this is likely reflective of the ability of these species to rapidly establish from the seed bank in Botany Bay.

Botany Bay has undergone significant disturbances and changes over the decades and, in its present state, is a highly modified estuary. These disturbances and changes have included dredging of the entrance, which has increased wave penetration and height, and extensive catchment development resulting in increased catchment runoff and inputs – all subsequently impacting on seagrass beds (Larkum and West 1990). Land reclamation in Botany Bay has altered coastal processes including sediment transport and shoreline erosional patterns (URS 2003), while armouring of shorelines to protect natural and built assets has altered wave climate and increased the risk of refraction to protected areas (Aijaz and Treloar 2003).

The Baseline Surveys for the Seagrass Monitoring Program were undertaken through a strong La Nina weather pattern that impacted on the eastern Australian coastline for 18-24 months, bringing above average rainfall that lowered salinities, increased turbidity levels and reduced light availability due to high sediment loads in Botany Bay for extended periods. Furthermore, this long-term weather pattern resulted in a number of significant weather and flood events within the Botany Bay catchment and coincided with a number of low pressure systems that formed off the Sydney Coast, resulting in large, powerful easterly swells entering Botany Bay. Turbidity is a major stressor of seagrass health, with light penetration considered one of the most important variables controlling the areal extent and abundance of seagrass in estuaries (Cardno 2018). These weather events appear to have had significant influence on seagrass assemblages and has likely driven decline of seagrasses within the Project Boundaries at both locations. At La Perouse, significant shoreline erosion occurred following storm and major Georges River flooding events that occurred during the Baseline 2 survey (i.e., between Feb to April 2022) (Niche 2022a) and the Baseline 3 survey (i.e., between July and August 2022) (Niche 2022b). Further, seagrass mapping had to be finalised and the drop camera survey completed after the major weather event in February / March 2022 (Baseline 2). This weather event included unprecedented rainfall for the Sydney Region that resulted in prolonged flooding and sedimentation, as well as extensive shoreline erosion as a result of refraction of waves into Frenchmans Bay from the seawall between Molineux Point and Bumbora Points. At the time of April 2022 sampling for the Baseline 2 survey at La Perouse, a usually uniform and gradually sloping seabed that supported low density seagrasses was unusually found to be highly variable, undulating with clear scour and deposition marks (Cummings Pers Ob). In contrast, mapping works for Baseline 2 at Kurnell were completed before the onset of that weather event, however drop camera surveys were not undertaken until April. Notably, the limited observations of seagrasses and the seabed made during the drop camera surveys at Kurnell in April did indicate that physical disturbance of the seabed appeared less acute in comparison with observations made at La Perouse. Data collected following that weather event across Baseline 2 and 3 indicated that large declines in seagrass extent occurred, especially at La Perouse in shallower nearshore areas with mixed *Halophila* and *Zostera* beds. Interestingly, beds and patches of *P. australis* were in most cases found to persist, although disturbance of the seabed was still perceptible. The Baseline data and observations indicate that the deeper-rooted *P. australis* (Waycott et al. 2014) is likely more tolerant and has greater capacity to persist in such adverse conditions than shallower rooted species such as *Halophila* and *Zostera*.

Other human-induced disturbances with potential to impact on seagrasses at La Perouse and Kurnell may include reduced water quality, vessel propeller scarring in shallow areas, and recreational and commercial vessel moorings. Reduced water quality can result in increased turbidity and nutrients, promoting growth of epiphytic and smothering algal species that can gradually reduce seagrass health (Abal and Dennison 1996), and increase susceptibility to leaf loss (Horn et al. 2009), especially for the slower growing species such as *P. australis*. Epiphyte data collected across the Baseline Surveys typically indicated that *P. australis* was consistently moderately- to heavily-fouled by epiphytic growth. This may lead to further declines in *P. australis* health in coming surveys or may be reflective of typical epiphytic growth that occurs on *P. australis* in Botany Bay. Small scale disturbances may also occur to *P. australis* beds from propeller scarring in shallow waters. Beds occurring in very shallow areas adjacent to sandy beaches are likely to be at most risk, especially in the reference site at La Perouse and shallower areas within the main bed to the west of the Project Boundary at Kurnell. Vessel moorings have been found to have significant impacts on seagrasses, especially *P. australis* in estuaries within the Sydney Region, including Botany Bay (West 2011). Throughout the Baseline Surveys various recreational vessel moorings were found to occur in seagrass habitat in Frenchmans Bay at La Perouse, while at Kurnell some commercial moorings appear to occur very close to and potentially encroach into the north-western side of the main *P. australis* bed. These moorings have potential to further impact on seagrasses, especially within the Project Boundary at La Perouse, where regular repositioning and or relocation appears to be occurring.

6.3 Suitability of the reference sites

6.3.1 *Halophila* / *Zostera* beds

At La Perouse the proposed reference sites (HZ-LP03 and HZ-LP04), which had slightly greater seagrass densities than the potential impact sites (HZ-LP01 and HZ-LP02), are considered to be suitable reference sites. The reference sites are expected to provide robust comparisons between Baseline Surveys and the during- and post- construction surveys.

At Kurnell the proposed reference sites (HZ-K07 and HZ-K08) were found to be similar in seagrass densities and variability to the potential impact sites further from shore (HZ-K05 and HZ-K06), however both seagrass density and variability were observed to be relatively much greater at the potential impact sites closer to shore (HZ-K09 and HZ-K10). The relative suitability of the latter sites for comparison with the reference sites, which are further from shore and not as variable, may be lower. Thus, interpretations of comparisons between Baseline surveys and during- and post-construction surveys will need to be done with some caution and consideration of these differences.

6.3.2 *Posidonia* beds

At La Perouse *P. australis* has a very limited areal extent, being mostly confined to small beds – one within and one outside the Project Boundary. The sizes of these beds are only sufficient for one monitoring site within each. As a result of this, replication of monitoring sites and capture of spatial variability inside and outside the Project Boundary at La Perouse is not possible. Thus, for these *P. australis* beds at La Perouse the BACI approach will not be as robust and so interpretation of analysis results will be more reliant on comparisons among periods and among surveys within periods. Furthermore, the reference site (PB-LP-12) is in very shallow water and close proximity to the beach, where it is more vulnerable to erosional impacts, wave energy and human disturbances. This may also be reflected by the increased variability in seagrass assemblage found at this site during the Baseline surveys. This will need to be considered when comparing any future changes in *P. australis* in this bed against patterns of change at the site within the Project Boundary.

At Kurnell, *P. australis* monitoring sites included two smaller beds – one inside the Project Boundary and one to the east of the Project Boundary – and eight sites within the main bed along two (east-west) transects that commence near the western side of the Project Boundary. The monitoring site to the east of the Project Boundary (PB-K10) was established as a potential reference site, as it provides for a measure of environmental disturbance as a result of easterly swell that may at times wrap around Kurnell Point and impact on *P. australis* within the eastern sections of the Project Boundary. Additional reference sites can be adopted from sites within the main bed to the west. This may include most of those western sites, with the two most easterly sites (PB-K01 and PB-K05) along these transects being possible exclusions.

7. Recommendations

7.1 Performance indicators

Data collected across the two years of Baseline surveys indicate that the spatial extent of *Halophila* and *Zostera* seagrasses can be highly variable and susceptible to substantial weather-event-induced declines within both Project Boundaries, while *P. australis* areal extent is much more stable with minimal decline, although some reductions in shoot density and small-scale edge effects around smaller patches have been evident. Furthermore, the significance of disturbances that have at times occurred across the Baseline period may have reduced the health and resilience of these seagrass assemblages (e.g., reductions in growth, reproductive potential, health and density) to well below average. Thus, there is the possibility of further declines as a result of similar or more extreme events that may occur into the post-baseline monitoring periods. In light of this, it must be acknowledged that the lower extreme of natural variability still remains unknown, and as such performance indicators may need to be adjusted to be reflective of results of those future surveys.

The performance measures will also need to consider any major environmental events, such as extremely destructive weather events, that may occur from now onwards, which have the inherent potential to impact on seagrass assemblages within the Survey Areas. For extreme events in particular this may require additional surveys in an attempt to capture any changes in seagrass extent and assemblages and separate their influence from any potential impacts attributable to the proposal.

7.1.1 Seagrass areal extent

The Seagrass Monitoring Program requires an acceptable rate of change in seagrass areal extent within the Project Boundary (excluding Construction Footprint and Buffer) to be established. This rate of change should also consider wider scale changes detected in the Survey Area, which are expected to be independent of future construction and operational activities within the Project Boundary.

The following performance indicators for seagrass areal extent are proposed. These have been chosen to allow for natural variability and the reduced precision when mapping large areas in GIS.

Any decrease in *Halophila* and *Zostera* extent within the Project Boundary (excluding the Buffer Area and Construction Footprint) shall not exceed 20% of:

- The areal extent measured in the Baseline 4 survey.
- Decline resulting from natural variability. To be estimated for the same period of time based on change in areal extent within the Survey Area (excluding Project Boundary).

Any decrease in *P. australis* areal extent within the Project Boundary (excluding the Buffer Area and Construction Footprint) shall not be greater than 10% of:

- The areal extent measured in the Baseline 4 survey.
- Decline resulting from natural variability. To be estimated for the same period of time based on change in areal extent within the Study Area (excluding Project Boundary)

7.1.2 *Halophila* and *Zostera* beds

The performance indicator for *Halophila* and *Zostera* beds shall be based on seagrass percent cover. Any decrease since the Baseline 4 survey at the potential impact sites shall not exceed 20%.

The BACI framework should also be suited to apply appropriate multivariate and univariate statistical procedures to detect more subtle changes that may potentially be attributable to the project and, additionally or alternatively, determine the contribution of natural variability and other independent stressors.

7.1.3 *Posidonia* beds

The performance indicator for seagrass shall be based on *P. australis* density. Any decrease since the Baseline 4 survey at the potential impact locations shall not exceed 10%. The potential impact locations should include the monitoring sites within the Project Boundary, and at Kurnell the most eastern sites along the two transects.

The BACI framework should also be suited to apply appropriate multivariate and univariate statistical procedures to detect more subtle changes that may potentially be attributable to the project. At Kurnell, additional statistical analysis to detect any changes in the relationship of *P. australis* density in the main bed with distance along the transects from the Construction Footprint should be investigated.

At Kurnell the potential impact site PB-K09 is mapped to encroach into the Buffer Area, any transplanting of areas of this bed that occur within the Buffer Area will need to be considered in future analysis of this site.

7.2 Modifications to the monitoring program

Consideration should be given to establish an additional *P. australis* bed monitoring site between the eastern perimeter of the Buffer Area and the monitoring site PB-K10.

7.3 Other

The period between the completion of the final Baseline survey (Baseline 4) and the first during construction survey should not exceed 15 months.

A decision will need to be made to either retain or transplant the area of the *P. australis* bed at monitoring site PB-K09 at Kurnell, which occurs within the Buffer Area. It is recommended that transplanting is avoided within 10 metres of the monitoring site to minimise edge effects.

During construction, detailed mapping of positions of all seabed works, anchors and moorings supported by real-time tracking of construction vessels and barges should be incorporated into the CEMP and considered when considering if any impacts can be attributed to the project.

8. Conclusions

In conclusion the baseline period of the Seagrass Monitoring Program has included four surveys completed over approximately two years. This has provided a measure of baseline variability in seagrass extent, coverage, composition and density within the Survey Areas at La Perouse and Kurnell, providing a robust BACI framework to investigate changes that may occur during and after the completion of construction.

The Baseline Surveys have found that the *Halophila* and *Zostera* seagrass beds that dominate the Survey Areas are highly variable in spatial and temporal extent, all the while having declined substantially over the last two years. In comparison, *P. australis* areal extent and condition remained relatively stable, although declines in shoot density were evident in some areas. The large-scale changes and reductions in seagrass extent in the Survey Area across the Baseline Surveys is attributed to environmental disturbances as a result of extreme weather events that occurred along the Australian East Coast over the last two years.

As of the completion of the Baseline 4 survey, seagrass within the Construction Footprint and Buffer Area at La Perouse was found to have an areal extent of 51 m² (all *Halophila* and *Zostera*), while at Kurnell the areal extent was 3,826 m², which included 258 m² of *P. australis* seagrass (Endangered Population). This 258 m² consists of typically low to moderate densities of *P. australis*. Furthermore, the *P. australis* shoot densities outside the established monitoring bed and patches were as low as 1-2 plants per m² and interspersed amongst other seagrasses that may dominate the seagrass community.

Performance measures have been derived based on the variability that has detected through Baseline Surveys. The performance measures will require regular review and interpretation with consideration of the statistical analysis, qualitative information sources, and major weather events with potential for environmental disturbances. These considerations will be essential to allow for any changes potentially attributable to the project to be accurately separated from those that represent natural variability and other disturbances that may act as stressors within the Survey Areas.

Our services

Ecology and biodiversity

Terrestrial
Freshwater
Marine and coastal
Research and monitoring
Wildlife Schools and training

Heritage management

Aboriginal heritage
Historical heritage
Conservation management
Community consultation
Archaeological, built and landscape values

Environmental management and approvals

Impact assessments
Development and activity approvals
Rehabilitation
Stakeholder consultation and facilitation
Project management

Environmental offsetting

Offset strategy and assessment (NSW, QLD, Commonwealth)
Accredited BAM assessors (NSW)
Biodiversity Stewardship Site Agreements (NSW)
Offset site establishment and management
Offset brokerage
Advanced Offset establishment (QLD)
