Disclaimer:

This report has been prepared in accordance with the scope of services described in the contract or agreement between Sandpiper Ecological Surveys (ABN 82 084 096 828) and Pacific Complete (PC). The report relies upon data, surveys and measurement obtained at the times and locations specified herein. The report has been prepared solely for PC and Sandpiper Ecological Surveys accepts no responsibility for its use by other parties. Sandpiper Ecological Surveys accepts no responsibility or liability for changes in context, meaning, conclusions or omissions caused by cutting, pasting or editing the report.

Executive Summary

Sandpiper Ecological Surveys (SES) was contracted by Transport for NSW (TfNSW) to implement the Woolgoolga to Ballina (W2B) Pacific Highway upgrade koala monitoring program in accordance with section 8 of the approved Koala Management Plan (KMP) (RMS version 4.4, July 2016). The broad aim of the monitoring program is to determine the effectiveness of mitigation measures implemented in Sections 1-11 of the upgrade for koalas. The following report presents results of year four (2020/21) of the monitoring program and builds upon results of years one, two and three monitoring (Sandpiper Ecological 2019a, 2019b, 2020).

Year four population surveys were completed at 99 sites – 50 in the Broadwater focal area (sections 8-9) and 49 in the Bagotville focal area (section 10) – during spring 2020 and autumn 2021. Fewer koalas were recorded in year 4 than year 3 in both focal areas. Bayesian estimation analyses of survey data suggest there is increasing evidence of a negative population trend at Broadwater and a stable population at Bagotville, even though the latter did have lower empirical counts and densities compared to Year 3. More years of population data are required to reduce the level of uncertainty and improve the level of confidence in determining population trends.

A prospective power analysis demonstrated that the koala population monitoring program at Bagotville was above the target level of statistical power (>0.7) whereas Broadwater was marginally below. Measures of power and statistical certainty remain low but are improving with each successive year of data. The modelling exercises confirmed the challenge of sampling populations at very low densities and drawing conclusions from sparse counts. Subsequent monitoring years should improve the precision of density estimates.

In working towards achieving the key mitigation measure for section 10 to reduce koala mortality by 4-8 individuals per year, TfNSW have implemented a predator control program, installed six vehicle-activated signs at road mortality hot-spots across the broader section 10 study area, fenced Wardell Road and the existing Pacific Highway and installed crossing structures on Wardell Road. These measures are in excess of those required by the Koala Management Plan. Since installation of fencing, no vehicle strikes have been reported on these two stretches of road compared to 10 in 2016/17 (FOK, unpublished data). There were no koala vehicle strikes within the focal population or recorded during the 2020 road mortality surveys conducted on the old Pacific Highway between Wardell Road and Coolgardie interchange, on Wardell Road between Gulbay Lane and Thurgates Lane or within sections 1-2 of the upgrade alignment. One incidental koala road mortality was recorded on 15/9/2020 within the Wells Crossing to Glenugie section of the Old Pacific Highway during construction, and a second road-kill was recorded in a fenced section of highway just south of the Devils Pulpit rest area in December 2020.

Camera monitoring of 14 koala crossing structures (i.e. underpasses) – 11 within sections 1-2 and three along Wardell Road – during spring 2020 revealed one complete crossing of a box culvert on Wardell Road. Koala scats were also recorded in habitat adjacent to the three underpass structures on Wardell Road. Complete crossings by fox increased over the three year monitoring period and peaked at 13.63 complete crossings/week at site K3 in Section 1. In 2020, foxes were recorded with prey on five occasions, however, the prey species could not be identified. The number of complete crossings by cats and dogs declined from year two to year 3.

Recover of habitat in the Bagotville focal area following the 2019 wildfire has been variable with several population monitoring transects showing signs of slow recovery in canopy vegetation.

Acknowledgements

We wish to thank the landholders who approved access to their properties to conduct the population surveys. Numerous monitoring sites are on private property, so landholder support is critical to achieving the goals of the monitoring program. We also extend appreciation to the Jali Local Aboriginal Land Council for their approval, support, and involvement with surveys within the Ngunya Jargoona IPA.

We would also like to extend a special note of appreciation to Friends of the Koala (FOK), particularly Maria Mathes, for her tireless work in supporting the persistence of koalas in the region.

The final report was improved by comments from Pacific Complete and TfNSW.

1. Introduction

1.1 Background

Sandpiper Ecological Surveys (Sandpiper) was contracted by Transport for NSW (TfNSW) to implement the Woolgoolga to Ballina (W2B) Pacific Highway upgrade koala monitoring program in accordance with section 8 of the approved Koala Management Plan (KMP) (RMS version 4.4, July 2016), excluding phased resource reduction. The primary aims of the monitoring program are to: determine the effectiveness of mitigation measures implemented in Sections 1-11 of the upgrade for koalas; and monitor trends in the size of koala populations surrounding the alignment at Broadwater (Sections 8-9) and Coolgardie-Bagotville (Section 10; hereafter referred to as Bagotville).

The three main mitigation measures requiring monitoring are koala-proof fencing along the length of the upgrade; connectivity structures along the length of the upgrade, and koala food tree plantings (focus mainly in Section 10). Both population monitoring areas are described as focal populations that could be adversely affected by the highway upgrade (RMS 2016). The two focal areas featured the highest density of koala records along the W2B alignment during environmental assessment population surveys (RMS 2016).

Baseline data on the focal koala populations have come from a variety of sources. Population surveys of the Broadwater focal area were conducted during 2014 and 2015 (Ecosure 2014, 2015). The Bagotville koala focal population has been the subject of detailed field and laboratory studies (see Phillips and Chang 2013; Phillips *et al.* 2015), which informed the preparation of a Population Viability Analysis (PVA) (Kavanagh 2016). The PVA was conducted in accordance with the Commonwealth Conditions of Approval (CoA 5 and CoA 7) and its outcomes have been used to guide management of koalas within this area.

The PVA for the Bagotville focal population indicated that this population is projected to decline significantly over the next 50 years (Kavanagh 2016) unless key threatening processes are controlled. Monitoring of this population is considered important to determine whether mitigation actions have been effective in slowing population decline. As such, the Bagotville focal population will be assessed against the PVA predictions. The Broadwater population, which was not subjected to a PVA, will be assessed against a statistically significant decline at year 15 compared with baseline survey values (RMS 2016).

1.2 Scope of works, program objectives and performance indicators

The monitoring program is designed to provide reliable information with which to inform management of koalas *Phascolarctos cinereus* along the highway upgrade. Koalas are listed as vulnerable in NSW by the NSW *Biodiversity Conservation Act 2016* (BC Act) the Commonwealth *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act). The objectives of the monitoring program for sections 1-11 of the highway upgrade as stated in the KMP and expanded upon in the Ecological Services Brief (RMS 2017) are described below. Those applicable to year 4 (2020/21) are shown in italics.

1. *Evaluate the success of mitigation measures against the performance measures and corrective actions.*
2. *Assess the effectiveness of the fauna crossing structures and fauna exclusion fencing to facilitate movement of koalas across the upgraded highway.*
3. Determine whether there is a statistically significant decline at year 15 compared with no decline in section 8-9.

4. Determine whether the corrective actions of the KMP have been triggered by estimated population trends in section 10 in accordance with predictions of the Population Viability Analysis.
5. Provide information that supports a program review by RMS at years 5 and 10 in accordance with the KMP (years 5, 10 & 15).
6. Assess effectiveness of the revegetation program in providing additional habitat for koalas.

Based on the above objectives, the success or otherwise of the monitoring program shall be determined by program performance against relevant performance indicators (PI). In addition, scat sampling will be conducted every three years in section 10 for the purposes of genetic analysis. These analyses aim to provide information on distribution and relatedness of individuals across the study area.

Table 8-4 in the KMP details eight performance indicators and their corresponding thresholds, corrective actions and agency responsible. The performance indicators and corrective actions relevant to the current year 4 report are described in Table 1.

Table 1: KMP performance indicators and corrective actions relevant to current report.

Performance indicator	Performance threshold	Corrective actions
1. Road mortality	<ul style="list-style-type: none"> • No injury to an individual koala as a result of vehicle strike across all upgraded sections. • Section 10: no koala road mortality within the fenced areas of the upgrade, on existing Pacific Highway or Wardell Road. 	<ul style="list-style-type: none"> • Examine fencing for breach or obstruction within 3 days of report & repair. • Retrofit exclusion fencing, or part there-of, with additional measures to deter koalas. • Section 10: RMS would consider erecting koala-proof fencing on Bruxner Hwy (a known koala road-kill black spot), in an effort to reduce koala mortality across the region.
2. Fauna crossing structures	<ul style="list-style-type: none"> • Evidence of at least one completed crossing by koalas at targeted fauna crossing structures. • Evidence of individual koalas using structures and/or breeding on either side of the highway, via scat analysis. • No evidence of high visitation/usage rates by exotic predators. 	<ul style="list-style-type: none"> • Review monitoring methods. Consider increasing frequency, intensity and duration, to ensure individuals are identified. • Check fauna furniture associated with underpass for damage and rectify. • Investigate habitat adjoining underpass. Consider improving habitat condition and connectivity.
3. Fauna exclusion fence	<ul style="list-style-type: none"> • No breaches in fauna exclusion fence. 	<ul style="list-style-type: none"> • Check fauna exclusion fencing and fauna crossing structures for damage/blockage and rectify.
4. Predator attack near fauna crossing structures	<ul style="list-style-type: none"> • No koala deaths or injuries due to predator attack in the vicinity of fauna crossing structures. 	<ul style="list-style-type: none"> • Where monitoring indicates that predators are a threat to koala movement through crossing structures, RMS will engage with North Coast LLS, NSW NPWS (Grafton), RLP Board (North East) & adjacent landowners to identify and implement strategies to reduce this predation risk.

The following report describes the methods and results of the year 4 (2020/21) monitoring period and includes an assessment of statistical power of population surveys going forward. It represents year 4 of population monitoring (construction phase) and year 3 of the crossing structure monitoring (operation phase in sections 1-2). It also represents year 4 road mortality/exclusion fence monitoring in section 10 along Wardell Road and the existing Pacific Highway and year 3 road mortality/exclusion fence monitoring in sections 1-2. Main alignment crossing structure monitoring is due to commence in spring 2021.

The report also addresses the monitoring objectives and assesses monitoring outcomes against the relevant performance indicators and whether thresholds have been breached and require corrective actions. The year 4 report builds upon years 1, 2 and 3 results. It will be used to inform a comprehensive program review at year 5.

2. Study area

The broader study area includes sections 1-11 of the W2B Pacific Highway upgrade alignment and adjoining habitat. The 155 km-long upgrade stretches from Woolgoolga in the south to Ballina in the north. It is wholly located within the NSW North Coast Bioregion, one of the most diverse in NSW (W2B Planning Alliance 2012). The project boundary is located within a landscape that has been either fragmented or cleared for agriculture and rural development although a substantial area of forest persists across the broader study area (W2B Planning Alliance 2012).

For the purposes of the year 4 report, monitoring activities were conducted in sections 1-2 (crossing structure and road mortality monitoring) and sections 8-10 (population monitoring and road mortality monitoring) (Figures 1 & 2). In sections 8-9, the Broadwater focal population area extends 3-5 km either side of an 11 km portion of the highway upgrade from Lang Hill (northern part of section 8) north to the Richmond River (including all of section 9; Figure 2). The Richmond River forms a major movement barrier to the west and north. Within section 10, the Bagotville koala focal population area extends 13.5 km north of the Richmond River and includes the localities of Bagotville and Coolgardie (Figure 2).

Figure 1: Sections 1-2 of the W2B Pacific Highway Upgrade.

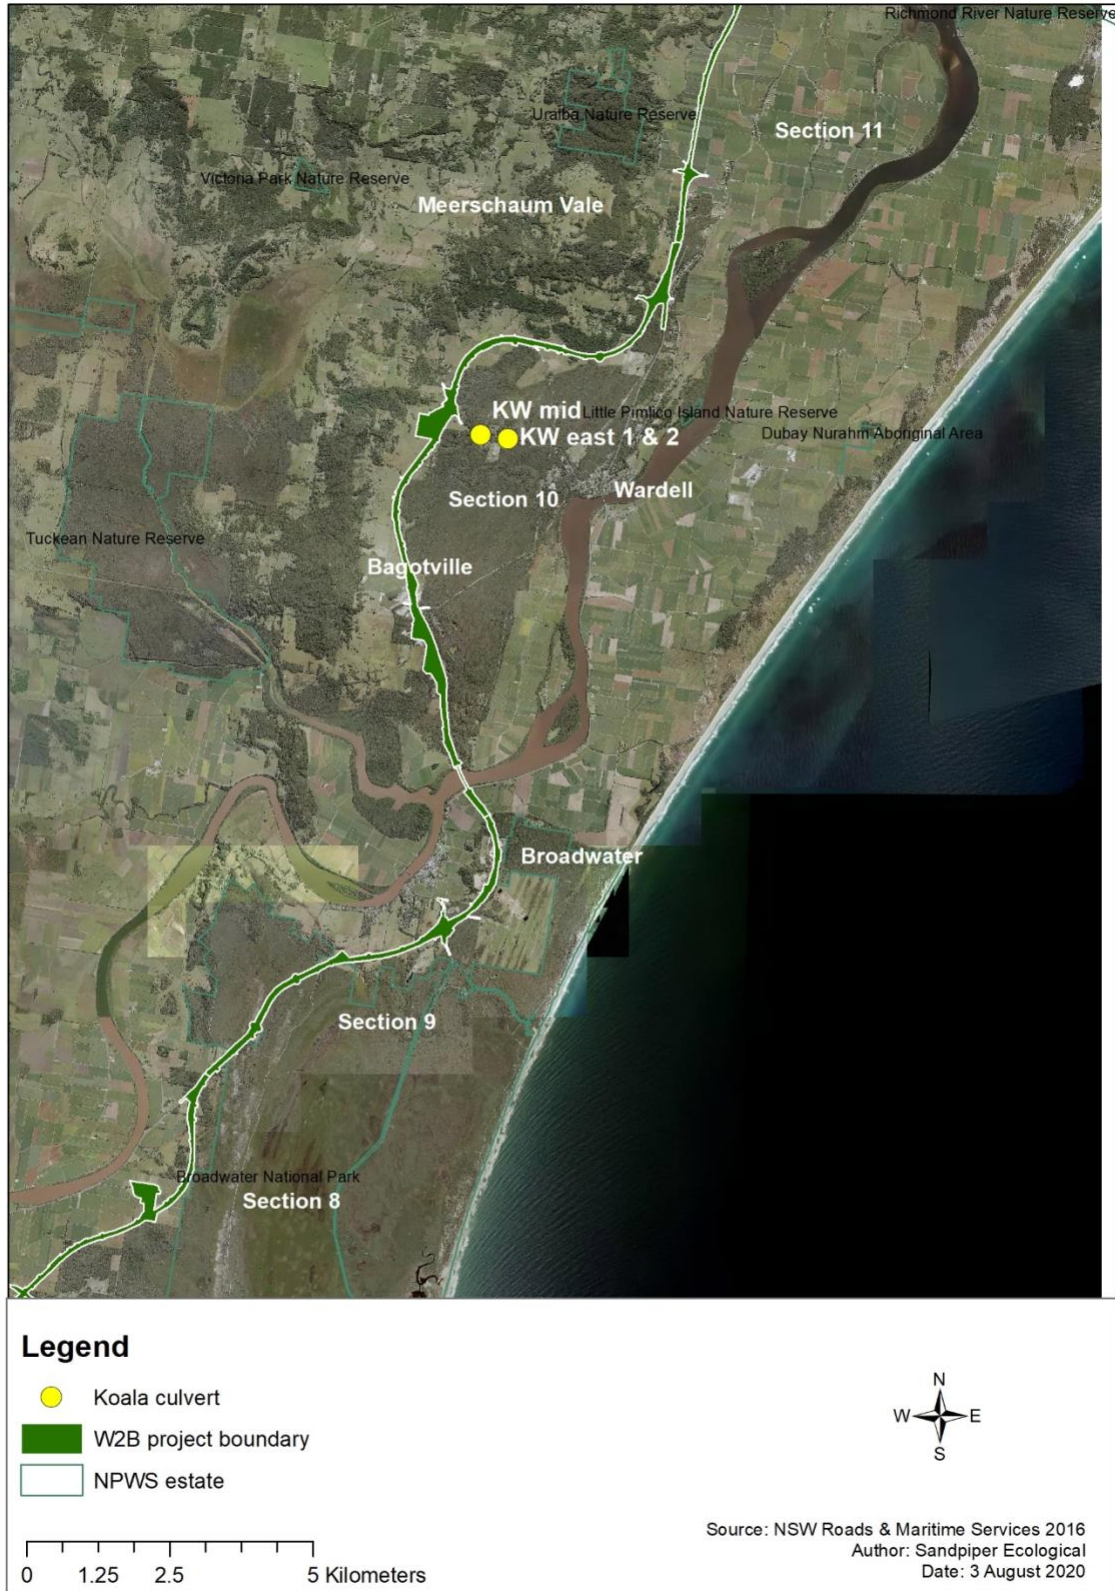

Figure 2: Sections 8-11 of the W2B Pacific Highway Upgrade.

3. Methods

3.1 Population surveys

Diurnal and nocturnal population surveys were conducted during spring 2020 and autumn/winter 2021. Surveys covered 100 sites (50 each in Broadwater and Bagotville) and were completed by teams of three ecologists experienced in koala surveys (Figures 3 and 4). At each site two direct count methods were used:

1. Transect searches

Direct counts on 250 m x 40 m transect (approximately 1 ha) involved three observers walking 20m apart – one on the centerline and one on each side. Observers were equipped with binoculars (& spotlight) and searched trees for koalas.

2. Radial searches

Direct counts within a radial area involved three observers slowly searching all trees within a 25m radius of the mid-point of the belt transect (approximately 0.196 ha). Radial areas and transects were conducted concurrently.

During year 1 and year 2 surveys, the same team completed diurnal followed by nocturnal surveys on the same day. To address concerns about inadequate survey independence, year 3 and 4 diurnal and nocturnal surveys were completed on non-consecutive days.

All koala observations were recorded with a handheld GPS unit and data collected on individual characteristics (e.g. sex, age class, health status, behaviour, identifying features), tree species and diameter at breast height of tree. Handheld spotlights were used to assist with nocturnal surveys.

Spring 2020 surveys were completed between 29 September and 3 December 2020. Diurnal surveys were generally completed between 0800 hours and 1830 hours and nocturnal surveys between 1900 hours and 2400 hours. Weather conditions were mostly fine during the survey period. Temperatures ranged from 15°C to 31°C and winds were variable.

Autumn 2021 population surveys were completed between 14 May and 24 June 2021. The autumn survey was delayed slightly to coincide with drone surveys, which will be reported on elsewhere. Diurnal surveys were generally completed between 0900 hours and 1700 hours and nocturnal surveys between 1730 hours and 2430 hours. Weather conditions were good for surveying koalas, with clear days and nights and occasional light wind recorded throughout. Temperatures ranged from 8°C to 23°C and light rain was recorded briefly on five occasions.

Figure 3: Broadwater (sections 8-9) sample sites.

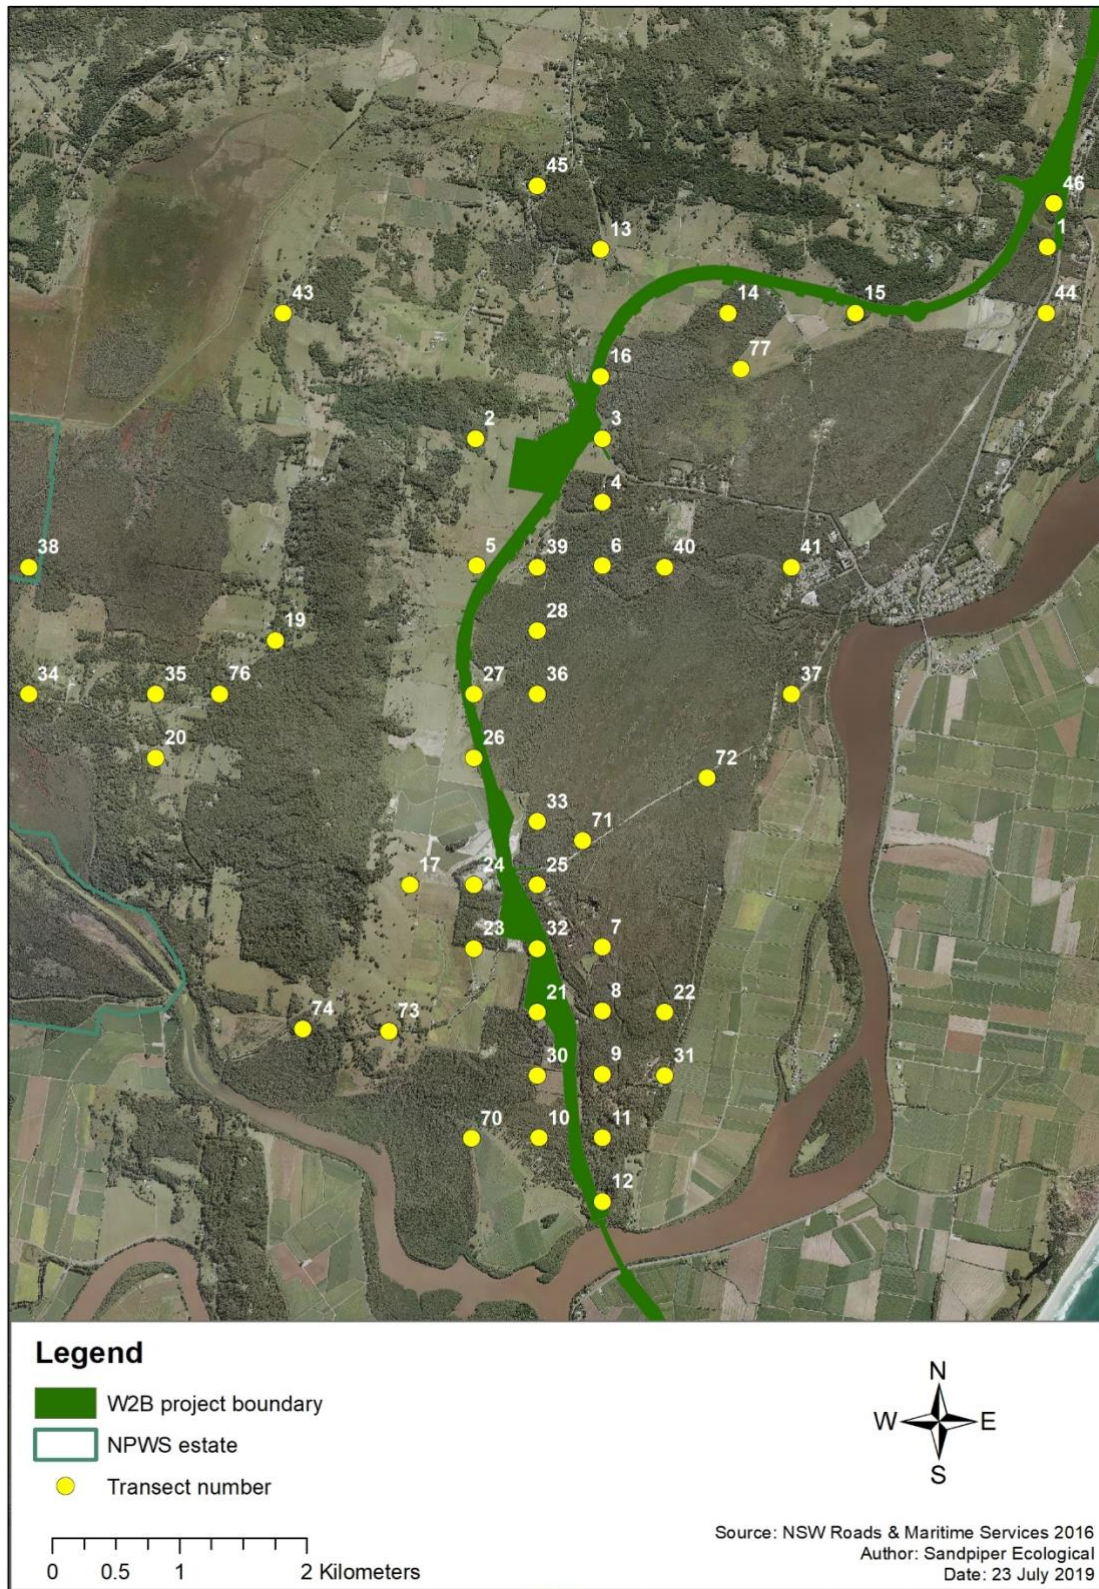

Figure 4: Bagotville (section 10) sample sites.

3.2 Koala density and population size estimates

A detailed report on statistical analysis of koala population data is provided by Rankin (2021) and included in Appendix A. Following is a summary of methods.

3.2.1 Bayesian modelling

A Bayesian estimation exercise was used to estimate densities at Broadwater and Bagotville for year 4 spring and autumn, and year 4 as a whole. The procedure included multi-model uncertainty for effects: night-time vs day-time effect, a radial- vs linear-transect effect; a seasonal effect; log-linear trend vs no trend vs each year having its own unique density, and five different amounts of over dispersion (excess count-variation). Each of these core specifications was repeated five times for five different Negative Binomial over dispersion priors (which broadly represented a spectrum of high-to-low over dispersion, the latter being equivalent to a Poisson). For this exercise, there were a total of 280 models. To acknowledge multi-model uncertainty, these models were model-averaged using posterior probabilities derived from the Watanabe-Akaike Information Criterion (Watanabe 2010, Gelman *et al.* 2014), as in previous reports (Sandpiper 2019a, 2019b, 2020).

In using the model-based approach, as described above, a Bayesian regression model is applied to the entire dataset to project the population back to Year zero based on the overall population trend. In so doing, this approach smooths-over the high natural-variation in counts and more accurately reflects the population density. The estimates include multiple sources of uncertainty resulting in conservative trend estimates. A disadvantage of this approach is that baseline and trend estimates need to be re-calculated as more data are acquired, which is why density estimates for the same years vary between reports. By contrast, a 'fixed baseline' approach employs a simple descriptive statistic, calculated as the mean (and standard deviation) of the raw counts during the baseline year. The baseline value is not updated as more data are acquired.

A disadvantage of the fixed-baseline approach is that due to the large natural-variation in koala counts (i.e. much year-on-year variation) and the sparsity of koala counts (i.e. few koalas in any year) the fixed-baseline reflects the random-variation during the baseline year, rather than the overall population density. Because the fixed baseline is sensitive to high variation in counts, it is more alarmist as a decision-making tool. In contrast, the model-based baseline focuses on the magnitude of the overall population trend, rather than the exact density in any one year. The trend is less sensitive to alarmist changes in koala counts although it may react quickly to a catastrophic drop in density, which is more likely with a fixed baseline approach. Due to high variability in counts between years and the focus on temporal population trends the model-based baseline approach was considered to be more consistent with the intent of the KMP/PVA.

For the Bagotville focal area, baseline density values derived from Bayesian modeling were then extrapolated across the total area of preferred koala habitat prior to clearing (i.e. 2,152 ha) and post-clearing/monitoring years (2,135 ha – as used in the PVA (Kavanagh 2016)), to derive a population size estimate for each period. To be consistent with the PVA population estimation methodology (Kavanagh 2016), a correction factor of 0.204 was then applied to Bagotville population estimates to account for the unsampled 0-1 year-old age cohort. The derived population estimates are referred to as 'revised population estimates'.

It should be noted that in applying the above approach, the Bagotville baseline population estimate presented in the PVA/KMP differs from the revised Bayesian modelling-derived baseline population estimate presented in the current report. Whereas population estimates are presented, determining population trends is focused on comparison of density estimates rather than population estimates. Focusing on density trends is more robust and reduces bias (Rhodes *et al.* 2015). Density estimates are also more reliable because the extrapolated area of preferred koala habitat differs between baseline and post-clearing (and differs between

actual area cleared (i.e. 28 ha) and that predicted in the PVA (i.e. 17 ha)) and its quality and extent will likely change during the 15 year-long monitoring program.

For the Broadwater focal area, which is not informed by a PVA and will be assessed according to a statistically significant decline at year 15, population trends are assessed according to density estimates.

3.2.2 Supplementary analysis to estimate trend in density estimates

A supplemental analysis was conducted to further investigate evidence for or against the presence of a trend in density estimates. The intent of the supplementary analysis was to complement and contextualise the main results. The supplementary analysis used frequentist Negative-Binomial GLMs models and performed model-averaging by AICc weights (Akaike 1974, 1998, Schwarz 1978) to estimate the trends at Broadwater and Bagotville.

These models can be thought of as pseudo-Bayesian models whereby the i) priors-on-parameters have been weakened to zero-influence, and ii) priors-on-model-probabilities are adaptive (i.e., they become more conservative with less data, and more liberal with more data). In other words, the AICc “reacts” faster to new data as compared to the static Bayesian priors used in the main analyses. The trade-off is that: the AICc may be more sensitive to developing trends, but may result in some over fitting and be alarmist, as compared to the Bayesian models with stronger priors.

3.3 Prospective power analysis

The KMP includes background information on use of a Power Analysis (PA) to determine minimum survey effort to reliably detect a decline in focal koala populations. It states, survey effort that achieved 70% power (or confidence) to detect a 30% decline in the Bagotville population was acceptable (RMS 2016). Using baseline data for each focal population and a diurnal search detection probability of 1.0/observer, the KMP PA determined that to achieve the 70%/30% target 50 survey sites within each focal area would need to be double sampled (i.e. two surveys/session) every six months (J. Rhodes unpub. data).

A subsequent prospective PA, which included current density data, would then be completed at the end of each reporting period to determine the minimum survey effort required going forward. Whereas the PA used to inform the KMP was based on a frequentist/null hypothesis testing approach, the prospective PA used in the current and previous reporting periods was based on a Bayesian estimation analysis.

The prospective analysis uses a Monte Carlo simulation procedure. The goal of the power analyses is to estimate the rate of Type-II errors (falsely rejecting the hypothesis of a trend, $H_a: \beta_t \neq 0$) while detecting a -30% decline from baseline levels at Broadwater and Bagotville between years 2015 and 2031. The error rates were conditional on:

1. a negative trend of -30% from baseline levels until Year 15 of monitoring;
2. a cap on the rate of Type-I errors at $\alpha \leq 0.3$;
3. a monitoring effort of 400 transects per year each at Broadwater and Bagotville (i.e. 50 sites surveyed twice/season and two seasons/year at each area);
4. marginal effects for survey-design factors (day-time/night-time, spring/autumn, line-transect/radial-search transects) empirically derived from the Bayesian analysis;
5. baseline koala densities derived from the Bayesian estimation analysis.

The prospective analyses were conducted in the same manner as previous reports with no supplements. Because the prospective analysis assumed the (simulated) existence of 15 years of data, it was considered less sensitive to prior distributions and issues of small sample-sizes. However, because the analysis is conditional on some empirically estimated features, the results are still somewhat sensitive to the estimated baseline conditions and the models used to estimate those conditions.

3.4 Crossing structure monitoring

3.4.1 Camera traps

Fourteen connectivity structures or underpasses (11 box culverts in sections 1-2; one single pipe, one twin pipe and one box culvert in section 10) were monitored for three months during spring/summer 2020 (Table 2). Underpasses monitored in sections 1-2 were as per year 3.

Box culverts in sections 1 and 2 featured timber post-and-rail (fauna) furniture through their length (Plate 1). Underpass floor substrate varied and included concrete (Kwest1, Kwest2 and Kwmid), concrete and raised gravel path (K1, K7-K10), timber mulch on concrete floor (K2-K5 and K11) and a combination of gravel and loose soil (K6). Underpass lengths at highway sites ranged from 18m at the split median (K8 & K9) to 57m at K4 (Table 2). Underpasses on Wardell Road were 15m long.

Table 2: Location of koala dedicated box culverts monitored in sections 1 and 2 (K1-11) and 10 (Kwest1, Kwest2, Kwmid). All culverts featured wooden post-and-rail structures except Kwmid, which featured a concrete ledge. Regrade refers to the % of underpass entrance visible from the horizontal level of the surrounding natural ground which is indicative of the perspective of an approaching terrestrial mammal.

Site No.	Chainage	Scn	Easting	Northing	Dimensions H x W (m)	Length (m)	Floor substrate	Regrade (% east/west)
K1	6890	1	515767	6681254	3 x 3	45	Raised gravel path & concrete	0/100
K2	8470	1	514567	6682196	3 x 3	51	Mulch on concrete	25/0
K3	8800	1	514201	6682384	3 x 3	50	Mulch on concrete	100/100
K4	11710	1	513204	6684852	3 x 3	57	Mulch on concrete	55/80

Plate 1: Box culverts monitored in sections 1-2 contained fauna furniture and some featured mulch spread over the concrete floor.

Underpasses were monitored with either Swift 3C or Swift Enduro cameras for three months during spring/summer 2020. For box culverts in sections 1 and 2, two cameras were mounted on the central post of the fauna furniture – one positioned to capture animals moving along the furniture and the other positioned approximately 400mm above ground level to capture animals moving along the floor (Plate 2). Both cameras were oriented east. For the culvert on Wardell Road, a camera was mounted at approximately 400mm above ground level and just inside the entrance of each end and oriented inwards (Plate 2). For pipes on Wardell Road, a camera was mounted to a tree or post within 5m of the entrance of each end (Plate 2). All cameras were contained in security cases with padlocks.

All cameras were installed on 17 and 18 September 2020 and were removed on 21 and 23 December 2020. Cameras were set on high sensitivity and programmed to take 10 seconds of video on activation. They were scheduled to turn on at 1800hr and turn off at 0600hr. Cameras were inspected during the middle of the session to change batteries and SD cards. Cameras affected by false triggers were assessed and, if necessary re-oriented to reduce false triggers. Twenty-two of the 28 cameras were active for the full duration of the sample period, three cameras were active for between 81 and 90% of the sample period, two cameras for 59% of the time, and one camera for 27% of the time. Cameras that were not active for the entire sample period experienced various issues including full memory, false triggers and card error (Table 3).

Camera monitoring targeting threatened mammals was also undertaken at nine koala underpasses (i.e. K1, K2, K4, K5, K7-11) during autumn/winter 2020 (i.e. 04/05/2020 – 08/07/2020) and summer 2021 (i.e. 05/01/2021 – 23/3/2021). Any koalas recorded during threatened mammal monitoring are reported on separately in the results section.

Plate 2: Typical underpass camera set-up: box culvert within sections 1-2 (A); Wardell Road box culvert – camera at each end (B); Wardell Road twin-pipe – camera at each end (C).

Table 3: Koala underpass camera monitoring effort during 2020. For Wardell Road underpasses, ‘floor/rail’ refers to ‘north/south’ camera. P = Pipe.

3.4.2 Camera image analysis

Camera images were uploaded to a desktop computer and viewed using Windows Photo Viewer. Data recorded included: site, date, time, species, number of images and image numbers. An ecologist reviewed all images, with reference to standard field guides (i.e. Menkhorst & Knight 2010; Menkhorst *et al.* 2017; Swan *et al.* 2004) and senior staff. A hierarchical approach was adopted for species identification, which included: species, genus or group. Identification accuracy was scored as either definite (90%+ certainty), probable (75-90% certainty), or possible (60-75% certainty).

To determine the likelihood of a culvert crossing, footage was scored according to the following criteria:

- *Complete crossing* - animal demonstrates directional movement along floor/furniture and does not return within 10 minutes.
- *Incomplete crossing* – animal demonstrates directional movement along floor/furniture but returns within 10 minutes or exhibits no directional movement along floor/furniture.

According to these definitions, a ‘complete crossing’ is inferred from display of strong directional movement and no evidence of return movement. For pipes, where cameras are installed at either end of the structure, the absence of concurrent footage at the other end of the pipe is presumed to be an instance of detection evasion. These definitions are consistent with other underpass investigations (see Goldingay *et al.* 2019), including other Pacific Highway upgrade sites (see Sandpiper 2017, 2018, 2019d, 2019e).

To control for variation in camera effort between sites, totals for complete crossings were converted to a per week value by dividing the number of crossings by the number of sample weeks. The number of sample weeks was derived by dividing the number of sample days by seven. Data were summarised according to underpass, native or introduced species, introduced predators (i.e. cat, dog, fox), and compared between monitoring years.

3.4.3 Scat and scratch searches

Scat and scratch searches were conducted at each underpass on three occasions during the monitoring period. Searches involved scanning the culvert floor and habitat within 50m of each underpass entrance for koala scats, predator scats and scratches on trees. Search effort was equivalent to 15 person-minutes/side. Any predator scats collected were sent to a recognised hair analyst for identification of mammal prey species.

3.5 Road mortality surveys and fauna fence inspections

Koala road mortality surveys were undertaken on two occasions, once in winter (9&10/7/2020) and once in spring (12&16/10/2020). Whereas year 1 and 2 surveys involved walking along the side of the highway, year 3 and 4 surveys were changed to car-based to address safety concerns. Car-based surveys were conducted in the section 10 areas along Wardell Road (Gulbay Lane to Thurgates Lane – 1.54 km), along the existing Pacific Highway (Carlyle Street to the Coolgardie interchange – 3.3 km) and along sections 1 and 2 (28.6 km).

Car-based surveys entailed a driver and passenger/observer travelling the length of the subject road in both directions. The survey vehicle featured a ‘Vehicle Frequently Stopping’ sign on the back and flashing light and travelled at 80-90 km/h in the left-hand lane. Surveys involved the passenger scanning the road surface and road shoulder for animal carcasses. When a carcass was observed, the vehicle would pull over at the nearest safe location and the passenger would walk back to inspect and identify the carcass from behind the guard rail/rope. The exact location of each carcass was recorded on a data sheet and referred to in subsequent surveys to avoid double-counting. Unidentified mammal carcasses were scored as either small (e.g. rodent, bat, glider, brush-tailed phascogale), medium (i.e. long-nosed potoroo, rufous bettong, bandicoot, cat, spotted-tail quoll, possum), or large (i.e. wallaby, kangaroo, dog, fox)

A hair sample was collected from any unidentifiable carcass suspected of being a threatened mammal. Samples were sent to a recognised hair analyst for identification. Road mortality results were supplemented by other data sources including incidental observations from Sandpiper staff while traveling focal roads, RMS staff, construction personnel and road mortality reports from Lismore-based Friends of the Koala (FOK). It is intended that these data be captured on the W2B Project Wide Koala Observations database curated by Pacific Complete. The fauna fence was inspected for breaches during road mortality surveys and during installation/retrieval of underpass cameras.

4. Results

4.1 Population survey koala observations

4.1.1 Broadwater focal area

During spring 2020 surveys, three koalas were observed on transects during diurnal searches and two on transects during nocturnal searches (Table 4; Figure 5). These included two males and two females and a recently independent young that was a probable male. No individuals were observed within radial plot areas. A further two koalas were observed incidentally off-transect while moving between sites. The body condition of individuals that could be viewed was generally good.

During autumn 2021 surveys, one koala were observed on transect during diurnal searches, and one during nocturnal surveys (Table 4). No individuals were recorded within radial plot areas. A further two koalas were observed incidentally off-transect while moving between sites. The body condition of individuals that could be viewed was good.

Full details of Broadwater koala observations are provided in Table B1, Appendix B.

Table 4: Broadwater focal area koala observations – baseline to year 4 (2020/21).

Survey session (no. of transects surveyed)	Diurnal transect	Nocturnal transect	Diurnal radial	Nocturnal radial	Incidental
Baseline (54)	7	NA	1	NA	1
Yr.1 spring (52)	1	2	0	0	2
Yr.1 autumn (50)	4	4	1	1	8
Yr.2 spring (50)	1	1	0	0	11
Yr.2 autumn (50)	1	2	0	0	3
Yr.3 spring (50)	2	3	0	0	6
Yr.3 autumn (50)	2	5	1	2	4
Yr.4 spring (50)	3	2	0	0	2
Yr4.autumn (50)	1	1	0	0	2

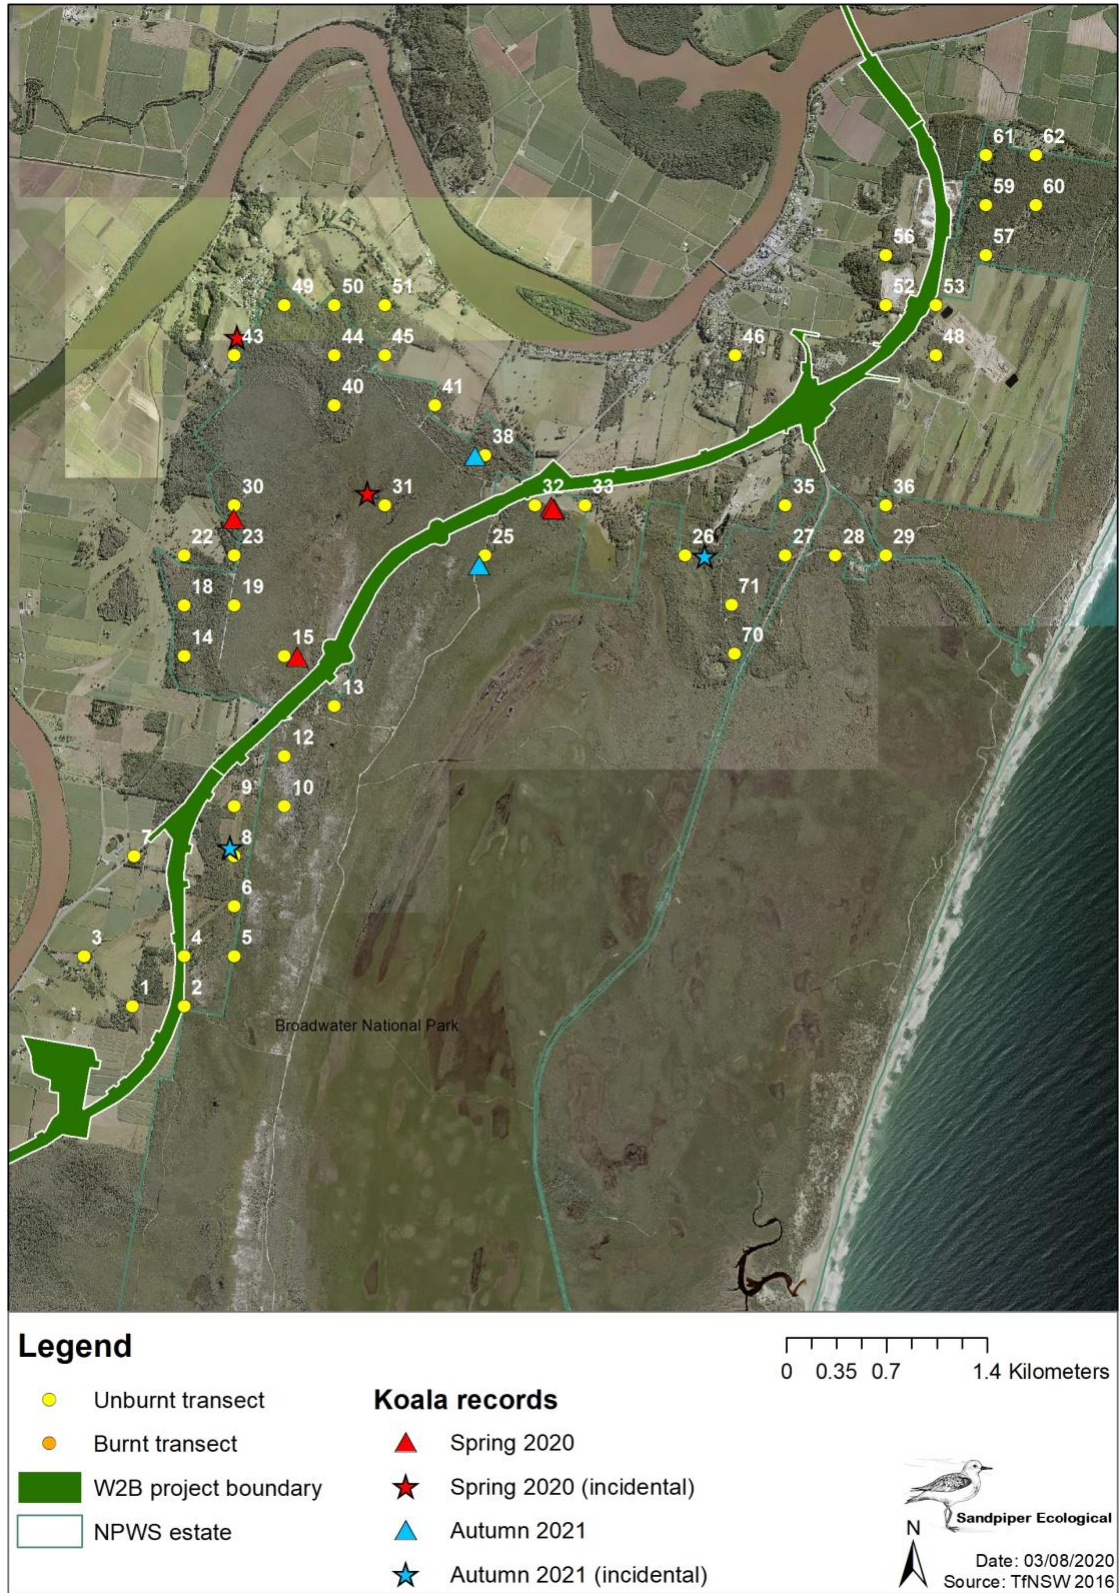

Figure 5: Broadwater survey sites and location of koalas observed during spring 2020 and autumn 2021 surveys.

4.1.2 Bagotville focal area

During spring 2020 surveys, three koalas were observed on transects during diurnal searches, one of which was also within a radial plot area (Table 5, Figure 6). During nocturnal surveys, five individuals were observed on transects and none within radial plot areas. One female was observed with a large back-young. A further four koalas were observed incidentally off-transect while moving between sites. The body condition of individuals' that could be viewed was generally good except one individual at site 20 had a dirty tail. A large carpet python was constricting the female with back young at site 74.

Transects affected by the spring 2019 wildfire were in varying stages of recovery. Canopy vegetation at transects 7, 22 and 41 had not recovered by the autumn 2021 survey. Over the spring and autumn surveys three koalas were recorded on previously burnt transects (#9, 33 & 36).

During autumn 2021 surveys, three koalas were observed on transect during diurnal searches and four during night searches (Table 5). No individuals were observed within radial plot areas. An adult female recorded on transect 36 had a back young. A further four koalas were observed incidentally off-transect while moving between sites. The body condition of individuals that could be viewed was generally good except four individuals (sites 20, 34, & 36) featured dirty tails.

Full details of Bagotville koala observations are provided in Table B2, Appendix B.

Table 5: Bagotville focal area koala observations - baseline to year 4 (2020/2021).

4.2 Koala density, population size estimate and trend estimate

4.2.1 Broadwater

Based on the Bayesian estimation analysis, the density estimate for spring 2020 was 0.047 koalas ha^{-1} (95%CI: 0.031-0.066) and autumn 2021 was 0.046 koalas ha^{-1} (95%CI: 0.031-0.065). Overall, the Year 4 density estimate for Broadwater was 0.046 koalas ha^{-1} (95%CI: 0.032-0.065). This compares to a modeled baseline density estimate of 0.060 (95%CI: 0.040-0.086) koalas ha^{-1} (Figure 7).

The estimated trend in density estimates at Broadwater was a 3.3%/year decline (SE: 0.043; 95%CI -0.127-0.028) with a 0.756 posterior probability of a decline. This is approximately double the decline that was estimated following the year three analyses. The hypothesis-testing posterior odds ratio (Bayes Factor) was 2.071, which is slight evidence of a declining trend. However, according to conventional categories, a value of 2.071 is considered 'barely worth mentioning' (Jeffreys 1961; Kass & Raftery 1995).

Figure 7: Comparison of Broadwater focal area density estimates (\pm 95%CI) for the modeled baseline and monitoring years.

4.2.2 Bagotville

Based on the Bayesian estimation analysis, the density estimate at Bagotville for spring 2020 was 0.081 koalas ha^{-1} (95%CI: 0.058-0.108) and for autumn 2021 was 0.080 koalas ha^{-1} (95%CI: 0.057-0.107). The overall Year 4 density estimate was 0.080 koalas ha^{-1} (95%CI: 0.058-0.106). This compares to a modeled baseline density estimate of 0.081 (95%CI: 0.057-0.111) koalas ha^{-1} (Figure 8). The estimated trend in density estimates at Bagotville was a 0.0%/year (SE: 0.025; 95%CI -0.061-0.060) with a 0.488 posterior probability of a decline. The hypothesis-testing posterior odds ratio (Bayes Factor) was 0.782, which is slight evidence against a decline. However, according to conventional categories, a value of 0.782 is considered 'barely worth mentioning' (Jeffreys 1961; Kass & Raftery 1995).

Extrapolated population size estimate for year 4 overall was 171 koalas (95%CI: 124-226) across 2,135 ha of preferred koala habitat (Figure 9). This compares to a modeled extrapolated baseline population estimate of 174 koalas (95%CI: 122-237) across 2,152 ha.

Figure 8: Comparison of Bagotville focal area density estimates (\pm 95%CI) for the modeled baseline and monitoring years.

Figure 9: Comparison of Bagotville focal area population estimates (\pm 95%CI) for the modeled baseline and monitoring years. Population estimates are based on 2152 ha (baseline) and 2135 ha (monitoring years) of preferred koala habitat, as informed by the PVA (Kavanagh 2016).

4.3 Power analysis

For a maximum Type-I error rate of 0.3, the estimated power at Bagotville and Broadwater was 0.726 and 0.667, respectively (Figure 10). For a maximum Type-I error rate of 0.35, the estimated power for Bagotville and Broadwater were 0.764 and 0.7, respectively.

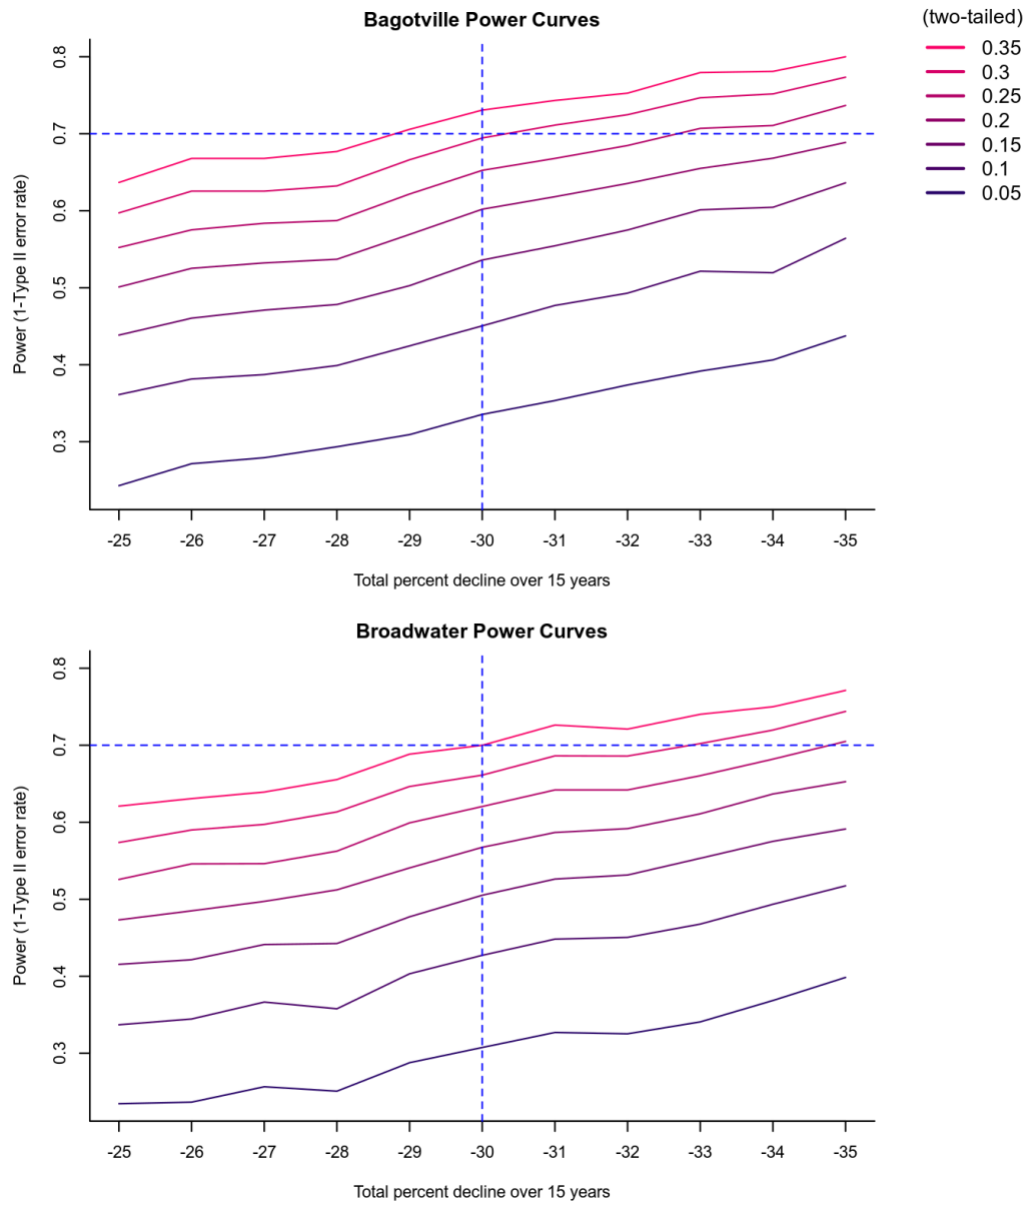

Figure 10: Statistical power to detect a 30% decline in baseline densities over a 15 year monitoring period for different maximum levels of Type-I errors (lines).

4.5 Crossing structure monitoring

4.5.1 Camera traps

Fauna crossings

Twenty species and four fauna groups were confirmed using koala underpasses during the spring/summer 2020 monitoring period (Table 6). Overall, 138.37 fauna detections/week (i.e. sum of complete {cc} and incomplete {ic} crossings/week) were recorded with the majority of detections (78.46%) being complete crossings (108.56cc/week) at a rate of 7.75 ± 7.74 cc/week/underpass (Table 6). Native species accounted for the majority of complete crossings at all underpasses except for K3 and K6, which were dominated by red fox *Vulpes vulpes* (Table 6). Complete crossings by native taxa, excluding rodent spp., small mammal spp., and *Rattus* spp., which may include native and/or introduced species, were highest at culverts K4 (16.08cc/week), K3 (13.87cc/week) and K5 (9.06cc/week) (Figure 11). Sites K7 and K6 recorded the lowest use by native fauna with 0.81cc and 0.66cc/week, respectively (Figure 11). *Antechinus* spp. was the most frequently detected species/fauna group. It was recorded in 10 of the 14 underpasses at an overall rate of 35.11cc/week (Table 6).

An adult koala was recorded making a complete southward crossing at the Wardell Road culvert (KWmid) on 27/9/2020 (Plate 3). Sex could not be determined and the individual did not show obvious signs of cystitis (i.e. wet/stained rump).

Other threatened species detected included rufous bettong *Aepyprymnus rufescens*, which was recorded making four complete eastward crossings at K11. No koalas were recorded during threatened mammal underpass monitoring in sections 1 and 2 during autumn/winter 2020 and summer 2021.

Full details of underpass camera detections are provided in Table C1, Appendix C.

Table 6: Number of complete and incomplete crossings/week by mammals at 14 koala underpasses during spring/summer 2019. Floor and fauna furniture crossings have been pooled. KW=Wardell Rd structure; C = complete crossing/week; I = incomplete crossing/week; P = present within structure; P = pipe structure; * = includes native &/or introduced species. ** = introduced species. Threatened species in bold.

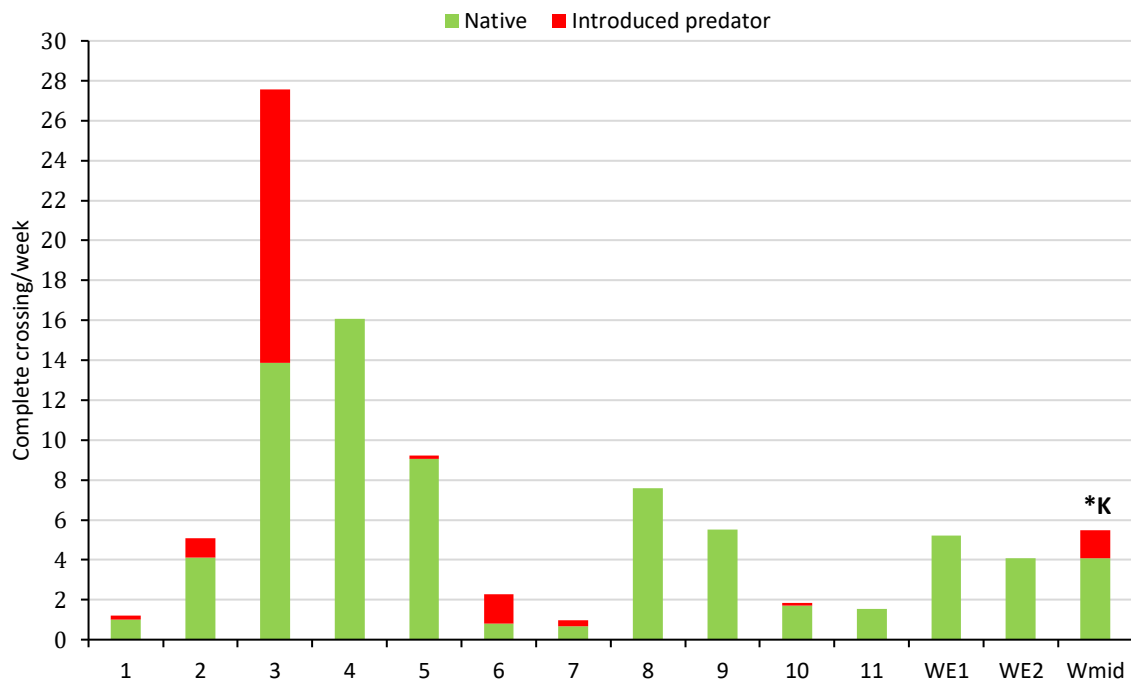

Figure 11: Complete crossings per week by native fauna and introduced predators (cat, dog, fox). *K = complete crossing by koala. Graph does not include taxa groups that include both native and/or introduced species (i.e. rodent spp., small mammal, and rattus spp.).

Plate 3: A koala was recorded making a southward crossing at KWmid underpass on 27 September 2020.

Introduced predator activity

Introduced predators (i.e. cat, fox & dog) were recorded at eight of the 14 koala underpasses at an average rate of 1.31 ± 3.61 cc/week/underpass (Table 6; Figure 11). Fox and cat *Felis catus* were recorded at six of the 14 sites, whereas dog *Canis lupus familiaris* was recorded at two sites (i.e. K5 and K6) (Table 6). Fox had the highest detection rate of 1.28 ± 3.59 cc/week/underpass with most crossings occurring at K3 (Figure 11; Table 6). Cat was recorded at a rate of 0.09 ± 0.14 cc/week/underpass and dog had the lowest detection rate of 0.02 ± 0.04 cc/week/underpass (Figure 12). Introduced predators were not recorded at K4, K8, K9, K11, WE1 and WE2. Footage showed fox with prey in K3, but it was unclear what the prey species was (Plate 4).

The mean number of introduced predators across all sites increased over the monitoring period, from 0.17 cc/week (± 0.20) in year 1 to 0.29 cc/week (± 0.37) in year 2 to 1.38 cc/week (± 3.59) in year 3 (Figure 13). In particular, the mean number of cc/week by foxes increased substantially between years two and three (Figure 12). Fox crossings peaked at site K3 where an average 13.63 cc/week were recorded (Table 11). Complete crossings by dog peaked in year 2 (Figure 12). Complete crossings/week/underpass by cat have decreased across years from 0.15 (± 0.20) in year 1, to 0.09 (± 0.11) in year 2, and 0.06 (± 0.10) (Figure 12).

Figure 12: Mean (+SD) number of complete crossings/underpass/week for introduced predators during year 1 (2018), year 2 (2019) and year 3 (2020).

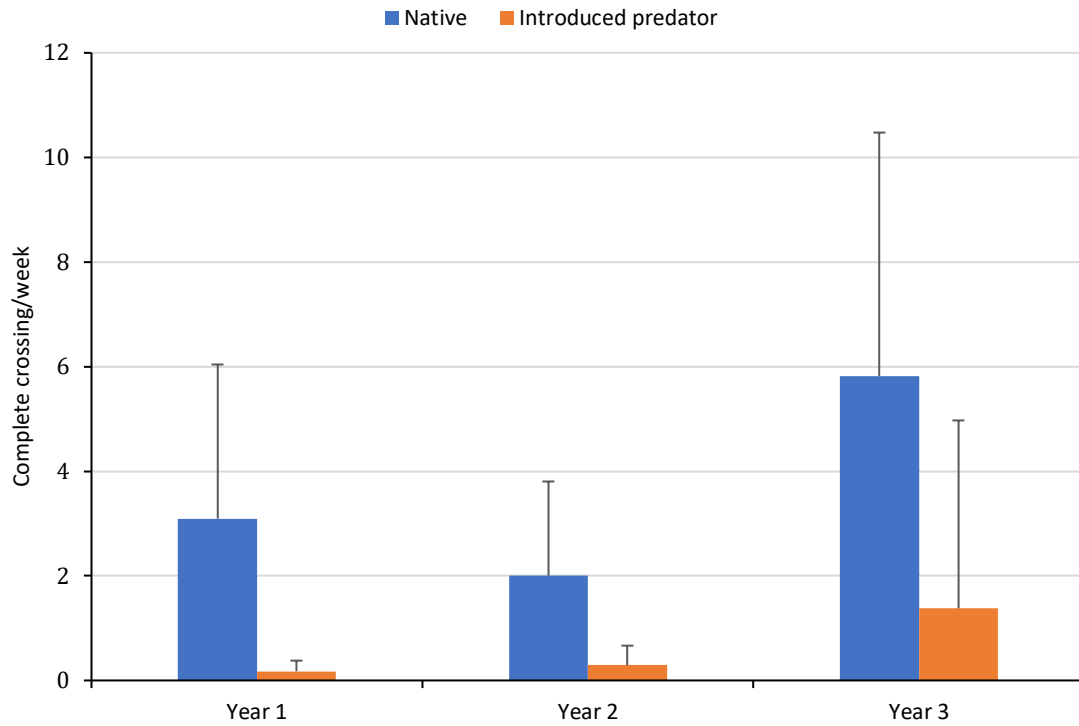

Figure 13: Mean (\pm SD) number of complete crossings/underpass/week for native species and introduced predator species (cat, dog, fox) during year 1 (2018), year 2 (2019) and year 3 (2020). Graph does not include taxa groups that include both native and/or introduced species (i.e. rodent spp., small mammal, and rattus spp.).

Plate 4: Fox recorded with prey in mouth at K3 on 6 November 2020.

4.5.2 Scat and scratch searches

Four species and nine fauna groups were recorded during scat and scratch searches (Table 7). K1, K3 and K11 had the highest number of species/groups with five, and K10 the lowest with one (Table 7). Koala scat was recorded on both sides of the Wardell Road culvert (KWmid) and pipes (KWe1 and KWe2).

Table 7: Scat and scratch records from three searches of culverts and adjacent habitat during the year 3 (2020) camera monitoring period. W=Wardell; P = pipe structure, X = scat record, * = scratch record, threatened species in bold.

Species/group	K1	K2	K3	K4	K5	K6	K7	K8	K9	K10	K11	KWe1 ^P / KWe2 ^P	KWmid

4.6 Road mortality surveys and fauna fence condition

4.6.1 Road mortality

Road mortality surveys detected 12 individuals representing 11 species/taxa groups at a rate of 0.18 individuals/km (Table 8). No koalas were recorded during the surveys. One incidental koala road mortality was recorded on 15/9/2020 within the Wells Crossing to Glenugie area of sections 1-2 at approximate location E 505541, N6694870 (GDA94). One additional koala road mortality was recorded in the Project Wide Koala Observations Register, curated by Pacific Complete, during the reporting period. It occurred on 1/12/20 at chainage 106750, approximately 350m south of the northbound rest area at Devils Pulpit. The fence was inspected in that area and no breaches were detected.

Mammals were the most frequently recorded taxa (n = 11), followed by birds (n = 1). Bandicoot spp. was the most frequently recorded group (n = 2). Road-kill rates were highest along the Old Pacific Highway (0.30 individuals/km) followed by sections 1-2 (0.17 individuals/km). No road mortalities were reported along Wardell Road (Table 8).

Full details of road mortality surveys are provided in Table D1, Appendix D.

Table 8: Fauna road mortalities recorded during two surveys conducted in spring/summer 2020. Records are pooled for the two surveys.

Location (survey distance)	Fauna recorded	Number of roadkill	Roadkill/km
Wardell Road (1.54 km)	Nil	0	0
Old pacific highway (3.3 km)	- Short-beaked echidna - Brushtail possum spp.	2	0.30
Sections 1-2 (28.6 km)	- Northern brown bandicoot - Bandicoot spp. x 2 - Eastern grey kangaroo - Medium mammal - European hare - Cat - Fox - Dog - Laughing kookaburra	10	0.17
Total (33.44 km)		12	0.18

4.6.2 Fauna fence

No detectable breaches were observed in fauna fence on Wardell Road, old Pacific Highway or along sections 1-2.

5. Discussion

5.1 Koala population surveys

5.1.1 Koala counts, density estimates and trend estimates

Broadwater

The aggregate count of koalas (i.e. spring + autumn) in the Broadwater focal area during year 4 were similar to levels recorded in year 2 and less than those recorded in the baseline, years 1 and 3. The number recorded during the baseline is expected to be higher due to greater survey effort at that time. The number recorded in spring year 4 was equivalent to spring year 3 but declined substantially during the autumn sample. Bayesian modelling of density, which largely controls for differences in survey effort between survey periods, suggests a downward trend from baseline to year 4 {i.e. from 0.060 koalas ha⁻¹ (95%CI: 0.040-0.086) to 0.046 koalas ha⁻¹ (95%CI: 0.032-0.065)}. Analysis shows there is increasing evidence of a downward trend, however, the strength of the trend remains weak.

Overall, at Broadwater, the estimated densities in year 4 were lower and the downward trend was more pronounced. The estimate of the year 4 density at Broadwater was 0.046 koalas/ha (SE: 0.008; CI: 0.032-0.065), which was lower than the preceding years. The estimated trend (-3.3%/a) was double the magnitude of the year 3 analysis (-1.6%/year). However, given the uncertainty in the estimates, the Bayes Factors do not provide strong evidence of a decline. Rankin (2021) also presented supplemental analysis using frequentist model-averaging. The AICc-based model-averaged estimate showed a 21.8%/year decline with a Fisher p-value against a decline of 0.094. This p-value is much lower than that recorded in year 3 (0.145) and is moving in the direction of rejecting the “no-trend” null hypothesis. Rankin (2021) points out “If the Broadwater population density in Year 5 is similar to or smaller than the Year 4 density, it could be that the future Year 5 p-value will reach the conventional cut-off of 0.05 (i.e., a 95% Type I error rate), at which point the null-hypothesis of “no trend” would be rejected.

Bagotville

Compared with Broadwater, counts for the Bagotville focal area have been relatively consistent across the survey period. The aggregate count (i.e. spring + autumn) in year 4 (15 individuals) was equivalent to years 1 (15 individuals) and 2 (14 individuals) and less than year 3 (20 individuals). Density estimates have been stable between the baseline {0.081/ha⁻¹ (95%CI: 0.057-0.111)} and year 4 {0.080/ha⁻¹ (95%CI: 0.058-0.106)}.

The per-year densities have lower overall standard errors, suggesting improving certainty in the estimates. There is no evidence of a trend, which was estimated to be 0.000%/year and had a high frequentist p-value. Compared to the Year 3 report, there is increasing confidence that Bagotville has little to no trend (Rankin 2021).

5.1.2 Power analysis

The current update to the prospective power analysis found that Bagotville has exceeded the 0.70 target, while Broadwater is marginally below the target threshold with an estimated power of 0.667. The value for Broadwater is a slight improvement to previous estimates. The power analysis relies heavily on the empirical estimates from the other analyses which, given the high uncertainty in the density estimates and covariate-effects, are likely contributing to a persistent inability to gain higher statistical power.

Improvements in statistical power has not been as large as the improvements in other statistical measures,

such as declining p-values or reductions in standard errors of density estimates. Statistical power is sensitive to the overall uncertainty in the entire system, because it incorporates empirical estimates of variance in the MCMC routine (Rankin 2021). It is likely that more transects would have to be sampled to meaningfully improve the power at Broadwater.

5.1.3 Statistical uncertainty

Following year 4 analysis a high level of uncertainty remains about the system (including sparse koala counts and uncertain estimates) making it difficult to resolve hypotheses and produce definitive statistical statements. The strength of predictions has increased slightly with each additional year of sampling, however, the high standard errors of density estimates, high p-values of trend estimates, moderate power, and low evidence ratios for Bayesian hypothesis tests contribute to statistical uncertainty. As noted previously more years of data-collection will alleviate some of these problems, however additional within-season sampling may be required to produce the requisite power and clarity.

5.1.4 Catastrophic events and other exogenous factors

As with any long-term population monitoring program, the focal koala populations may be affected by a range of catastrophic events and exogenous factors outside of the control of the upgrade project. The wildfire that burnt through approximately 470 ha of the Ngunya Jargoona IPA was one such catastrophic event. It followed a wildfire in the eastern part of the Ngunya Jargoona IPA that burnt out 350 ha in September 2017. The PVA modelling for Bagotville estimated catastrophic fire events at a frequency of once every 35 years with each event encompassing only 10% (i.e. 215 ha) of the 2152 ha study area (Kavanagh 2016). However, within the first three years of the monitoring program wildfire has occurred twice and encompassed 16-22% of the study area. This suggests that the frequency and extent of wildfire modelled in the PVA may have been underestimated.

The other ‘catastrophe’ input in the PVA is drought (Kavanagh 2016). Drought is modelled to occur at a frequency of every 4-5 years. Records from the closest long-term weather station (i.e. Bureau of Meteorology Weather Station No. 58171, Meerschaum Vale) show that for the first three years of the monitoring program (i.e. July 2017 to June 2020) annual rainfall totals were 16.4% - 21.8% below average. Moreover, the calendar year of 2019 was 44.2% below average and the later half of 2019 was by Bureau of Meteorology definitions a serious to severe drought. It was also the lowest annual rainfall total on record (since records began in 1977). Further monitoring years will be required to determine the veracity of PVA drought predictions.

Other exogenous factors may include local land development, clearing activities, euthanasia of diseased individuals, and the emergence of other diseases and/or pathogens. One such pathogen – myrtle rust – was observed in and around site 14 during autumn 2020 surveys. Myrtle rust is a fungal pathogen that infects plants in the Myrtaceae family, which includes plants of the genus *Eucalyptus* (DPI NSW 2015). The potential impact on koalas would primarily be the loss of food resources within infected areas. Infestations were not observed at other sites. To reduce the risk of spreading myrtle rust the site 14 transect was shifted from the infestation area prior to the spring year 4 survey.

5.23 Use of crossing structures

5.3.1 Koalas

The absence of koala detections in underpasses within section 1-2 during the spring/summer 2020 monitoring period is broadly consistent with results of 2018 and 2019 monitoring when one and zero crossings were recorded in each year respectively. Absent or infrequent use of underpasses by koalas has also been reported at other monitoring sites along the Pacific Highway upgrade (e.g. Sandpiper 2017, 2018, 2019d, 2019e). This is

particularly so for sections featuring low koala densities in the adjoining habitat, which is the case for sections 1 and 2 (RMS 2016). In fact, no scats were detected in habitat adjoining underpasses in sections 1 and 2.

Conversely, monitoring at sites with a resident koala population has shown rapid and consistent use of underpasses (Sandpiper Ecological 2020a). This is reflected in results at Wardell Road (section 10) where koala scats were recorded in habitat on both sides of the road at all three underpass structures and an individual was detected making a complete crossing of the box culvert on one occasion. The record was a healthy individual using the raised concrete ledge to move south across the road.

Whilst limited evidence of koalas using structures in S1 and 2 has been recorded these sections were not considered likely to support koalas and findings are consistent with results of monitoring for the Glenugie Upgrade where one koala crossing was recorded in three years of sampling (Sandpiper Ecological 2017).

5.3.2 Exotic predators

Introduced predators (cat, fox, dog) were detected in nine of the 14 underpasses, which was lower than in 2019 when they were recorded in 12 of 14 structures. The frequency of crossings by dogs and cats decreased from year 2 (2019) to year 3 (2020), whilst fox crossings increased substantially from 0.11/week in 2019 to 1.28/week in 2020. Foxes were recorded at six structures including KWmid where a koala was recorded. Fox activity peaked at K3 with 13.63 cc/week. Foxes were recorded moving through K3 with prey on five occasions, however, the species of prey could not be confirmed.

Cat crossings were recorded at six sites, including the Wardell Road box culvert where a koala was detected, and peaked at K1 (0.44cc/week) and K6 (0.37cc/week). There has been a steady decline in cat use across all sites with crossing/week declined from 0.15 in 2018 to 0.09 in 2019 and 0.06 in 2020. Cats pose a low predation risk and we are not aware of any substantiated reports of koala predation by cats. Similarly, while fox was detected at six structures, there is limited evidence to verify that foxes predate koalas although back young may be vulnerable when mothers are moving across the ground.

In contrast, predation of koalas by wild and domestic dogs is well established (e.g. Lunney *et al.* 2004, 2007). Dogs were recorded at two sites in 2020, K5 and K6 and use of these structures was relatively low at 0.07cc/week and 0.15cc/week respectively. This result contrasts the 2019 results when frequent use by several individual dogs was recorded at K1 in section 1 (Sandpiper Ecological 2020b). In 2019, K1 contributed 95% of all recorded dog crossings. No dogs were recorded within the Wardell Road underpasses during camera monitoring in 2020.

Based on the results of year 2 monitoring, Sandpiper Ecological (2020b) recommended targeted predator control at K1. Based on year 3 results such action was unwarranted and findings highlight the importance of considering predator activity over multiple years before implementing control.

5.3.3 Performance indicators

Fauna crossing structures.

1. Evidence of at least one completed crossing by koalas at targeted fauna crossing structures.
 - a. *One completed crossing at KWmid (Wardell road culvert).*
 - b. *A complete crossing by a koala was recorded at site K5 on 26/10/2018.*
2. Evidence of individual koalas using structures and/or breeding on either side of the highway, via scat analysis.
 - a. *Scats were detected in habitat adjacent to three structures on Wardell road (KWe1, KWe2 and KWmid)*
 - b. *DNA analysis of scats collected near underpasses will recommence in 2021.*
3. No evidence of high visitation/usage by exotic predators.

- a. *Low frequency use of most underpasses by cats and dogs; high frequency use of K3 by foxes.*

Predator attack near fauna crossing structures.

1. No koala deaths or injuries due to predator attack in the vicinity of fauna crossing structures.
 - a. *No evidence of koala deaths/injuries due to predator attack was recorded.*

5.4 Road mortality and fauna fence

5.4.1 Road mortality

Road mortality rates declined from 1.37 individuals/km during year 1 to 0.62 individuals/km in year 2 and 0.18 individuals/km in year 3. The decline in road mortality rates from years 1 to 3 may be an artefact of reduced rate of detection with car-based surveys although detectability trials of car-based surveys found them to be highly effective at detecting medium-sized fauna (Taylor & Goldingay 2004) and the same methods were applied in years two and three. No koala mortalities were recorded along survey road sections although two koala road mortalities were reported for the broader study area (i.e. W2B S1-11). This finding is consistent with year 1 (1 individual) and year 2 (2 individuals). The two mortalities in S1-11 equate to a density 0.012 individuals/km, which is less than half the rate 0.026 ind/km cited by RMS (2016) for the old Pacific Highway in S10. Of the two mortalities recorded in 2020/21, one occurred in an area with no exclusion fence.

5.4.2 Fauna fence

The fauna fence was generally in good repair, although observation has shown that koalas can move through small gaps at gates and the point of entry may not always be obvious. No breach of the fauna fence was detected near chainage 106750 where a road-killed individual was recorded.

5.4.3 Performance indicators

Road mortality

1. No injury to an individual koala as a result of vehicle strike across all upgraded sections.
 - a. *Two koalas were struck and killed during the 2020/21 sample period.*
2. Section 10: no koala road mortality within the fenced areas of the upgrade, on existing Pacific Highway or Wardell Road.
 - a. *No koala road mortalities observed or reported.*

Fauna exclusion fence.

1. No breaches in fauna exclusion.
 - a. *Exclusion fence in the vicinity of the road-kill at chainage 106750 was inspected and no gaps in the fauna fence were recorded.*
 - b. *The presence of a koala within the alignment suggests that the fence may have been breached, however, there is also a gap in the exclusion fence at the nearby rest area.*

6. Recommendations

The following actions are recommended for year five of the koala monitoring program:

1. Continue the koala population monitoring program in year 5 (2021/22) and include a program review in the year 5 report.
2. Cease monitoring of structures K1-K11 in Sections 1 and 2 as the three year monitoring requirement has been completed.

Year 4 Monitoring Report: Updated Analysis of the W2B Koala Monitoring Programs in Bagotville and Broadwater, NSW, Australia.

10 September 2021

By Robert W Rankin, Ph.D.

under contract by Rankin Holdings, 1035179 Ontario Inc.

1 Summary

This report provides an updated analysis for Year 4 of the W2B Pacific Highway Upgrade koala population monitoring program being conducted in sections 8/9 (Broadwater) and 10 (Bagotville) in accordance with the Koala Management Plan (RMS 2017). The analyses have been updated using the latest data following completion of the spring 2020 and autumn 2021 field seasons.

This report presents four analyses: i) estimation of koala densities; ii) estimation of possible emerging trends; iii) hypothesis-testing of a night-time vs. day-time effect; and iv) an updated prospective power analysis.

Summary of results:

- In general, the estimates of trends, densities and power continue to show modest increases in statistical certainty and an improved ability to detect trends, but are still nonetheless high in overall statistical uncertainty in absolute terms.
- There was an error detected in the analytical scripts for the Year 3 report (but not prior reports) which miscalculated the densities at radial surveys at Bagotville. These affected Year 3 Bagotville density estimates but not trends. The error has been corrected and the updated Bagotville densities in this report are correct.
- The estimated population densities at Broadwater and Bagotville for Year 4 2020/21 were, respectively, 0.046 koala/ha (SE: 0.008; 95%CI: 0.032-0.065) and 0.080 (SE: 0.012; 95%CI: 0.058-0.106). The estimate for Year 4 at Broadwater is lower than the Year 3 estimate of 0.049 (SE: 0.008; CI: 0.035-0.066), while Bagotville shows little-to-no change.
- Broadwater has an estimated trend of -3.3%/year ($\bar{\beta}_t = -0.033$ per year; SE: 0.043; 95%CI -0.127-0.028). The estimated trend at Bagotville was 0.0%/year increase ($\bar{\beta}_t = 0.000$ per year; SE: 0.025; 95%CI -0.061-0.060). There was no evidence of a significant trend, according to Bayesian hypothesis testing. The Frequentist methods continue to estimate a steep decline at Broadwater.

- There was slight evidence *against* the presence of a "night-time effect", i.e., there was no meaningful difference between night-time and day-time surveys. The statistical evidence (Bayes Factor) to support this conclusion is stronger than the conclusion in the Year 3 analysis.
- The estimated power at Broadwater and Bagotville were and 0.667 and 0.726, respectively, which are slight improvements from the Year 3 report.

2 Introduction

2.1 Background

This report presents the fourth statistical analysis of koala densities and trends, commissioned in support of Sandpiper Ecological Survey's ongoing koala population monitoring in sections 8/9 (Broadwater) and 10 (Bagotville) of the W2B Pacific Highway Upgrade which are being conducted in accordance with the Koala Management Plan (RMS 2017). The intent of these analyses is to evaluate the program's goal of being able to detect a potentially large decline in koala densities. Specifically, the survey effort and statistical modelling should be able to detect a 30% decline over 15 years with a power of at least 70% and a Type-I error rate (α) of 0.30.

This report updates the statistical analyses of previous reports, including a Bayesian trend analysis and simulation-based power-analysis. The methodological details have been described in previous reports (Sandpiper Ecological 2020), and will be summarised here.

2.2 Objectives

There are four objectives addressed in this report:

- Objective #1. Update the koala population density estimates at Broadwater and Bagotville for Year 4, including segregated estimates for Spring (2020), Autumn (2021), and a pooled estimate for Year 4 (both seasons).
- Objective #2. Update the trend analyses and evaluate the evidence of an emerging trend at either Broadwater or Bagotville. This objective has been addressed according to the original Bayesian trend estimation method proposed in the original report from Year 1 (Sandpiper Ecological 2019a), and has been supplemented with an alternative frequentist paradigm (based on the AICc) that was explored in the Year 2 and Year 3 reports (Sandpiper Ecological 2019b; Sandpiper Ecological 2020).
- Objective #3. Evaluate whether there is an important difference between densities during night-time vs. day-time surveys.
- Objective #4. Update the prospective power analyses; determine whether the program can detect a 30% decline over 15 years with a power of 0.70 ($\alpha \leq 0.3$ and $power > 0.3$).

3 Important Updates

There are two important methodological updates for the Year 4 analysis compared to the Year 3 report:

3.1 Multi-model Inference: Accounting for Inter-Annual Differences

Throughout these reports, we have employed a model-averaging approach to pool estimates from multiple models (trend vs no trend, night-time effect vs no-effect, and more) based on their predictive accuracy.

Previously, the inter-annual variation in counts/densities was parametrised according to three possibilities: i) no trend, ii) trend, iii) no trend but each year was allowed to have an independent density (i.e., inter-annual variation).

Because of the availability of 5 years of count data, the specification of option (iii) has been revised to include both a trend as well as inter-annual variation, resulting in the following three possibilities: i) no trend, ii) trend, iii) inter-annual variation around a dominant trend.

This change makes option (iii) more realistic, given that most ecological processes include both inter-annual variation as well as a long-term trend. This updated specification is currently only possible for the Bayesian models.

3.2 Error in Year 3 Areas at Bagotville

An error was detected and corrected in how the raw spreadsheet data was being imported for the Bagotville transect areas. Prior data-sheets recorded per-year and per-transect areas separately, whereas the Year 3 and Year 4 data-sheets consolidated the per-transect areas into a single column in the datasheet. An error resulted in declaring the radial-search areas to be the same as the per-row transect-areas at Bagotville, whereas these should be 0.19ha for the radial search-areas.

Because the error was consistent across all years in the Year 3 data-sheet, there should not have been a large effect on the trend analyses and power analyses, but the Year 3 reported densities at Bagotville at the radial-surveys were not correct. For instance, Tables 1 & 2 in Section 4.2 of the Year 3 report are now known to be incorrect, for Bagotville.

These errors have been corrected for the Year 4 analyses. The updated and correct densities for Bagotville are included in the results.

4 Methods

The following sections will review major methodological features of the analyses. More details about the methodologies can be found in previous reports (see Sandpiper Ecological 2019a, b & 2020).

4.1 Statistical Model for Counts and Density

We are interested in modelling koala density $\eta_{l,t,j}$, using observations of the counts of koalas $y_{l,t,j}$ at location l (*Broadwater vs. Bagotville*), in year t , at transect j . Each transect j also has a record for its area A_j , and indicator variables X_j denoting whether the survey occurred at night-time or daytime, whether it was a radial survey or line-transect, and whether the survey happened during the autumn or spring. We combine these variables into a log-linear GLM statistical model according to the following reasoning. We start with the formula for density (number of koalas per area):

$$\eta_{l,t,j} = \frac{N_{l,t,j}}{A_{l,t,j}} \iff N_{l,t,j} = \eta_{l,t,j} A_{l,t,j}$$

Where η is the density of koalas at location l at time t and transect j ; N is the (true) number of koalas; and A is the area at transect j . We substitute N for its statistical expectation $E[y]$ (from a count distribution like the Negative Binomial), and take the natural logarithm of both sides to yield:

$$\begin{aligned} \mathbb{E}[y]_{l,t,j} &= \eta_{l,t,j} \cdot A_{l,t,j} \\ \log(\mathbb{E}[y]_{l,t,j}) &= \log(\eta_{l,t,j}) + \log(A_{l,t,j}) \end{aligned}$$

Finally, we substitute the density term η for its linear-model decomposition ($\beta^T \mathbf{x}_{l,t,j}$), thus arriving at our familiar equation of a line with an area offset.

$$\log(\mathbb{E}[y]_{l,t,j}) = \beta^T \mathbf{x}_{l,t,j} + \log(A_{l,t,j})$$

This means we can use a Negative Binomial distribution to model counts y and perform linear regression to estimate parameters β , as well as estimate other interesting quantities, such as the koala densities for each year, location and season. Estimating the densities per year satisfies Objective #1, while a trend parameter in β helps satisfy Objective #2.

4.2 Parameters, Priors and MCMC

The regression parameters β and the covariates in the model-matrix X include different features like: year, daytime vs. night-time effect, radial- vs. line-transects, and a seasonal effect. According to the Bayesian estimation paradigm, each of these parameters requires a prior distribution.

The priors used in this analysis were the same as used in the Year 1, 2 and 3 reports. The motivation and description of the priors can be found in the Year 1 report; the values are reported here without extensive expository detail.

Priors. The prior distribution on the trend parameters were set to $\pi(\beta_{t,l}) = \mathcal{N}(0, 0.05^2)$. The prior on the (log) baseline density at Bagotville was given a Gaussian distribution $\pi(\beta_0) = \mathcal{N}(\log(0.091), 0.41^2)$. The prior on the marginal difference between the Broadwater log-density vs. Bagotville was $\pi(\beta_l) = \mathcal{N}(0, 0.54^2)$. The prior on the marginal affect of the radial- vs. line-transects was $\pi(\beta_r) = \mathcal{N}(0, 0.54^2)$. The marginal effects of night-time vs. day-time, and autumn vs. spring, had the same prior mean and variance. Finally, for the Negative Binomial over dispersion parameter θ , a Gamma prior was used with a prior mean of 5. The strength of this prior was determined according to a model-selection exercise (see next section) where the shape and rate parameters of the Gamma distribution were: $\{(5,1), (10,2), (20,4), (40,8), (500,100)\}$, thereby allowing the models to vary between a near-Poisson distribution, or an overdispersed Negative-Binomial distribution.

MCMC. Given the data and the priors, the regression coefficients β could be estimated according to Monte Carlo Markov Chain (MCMC) algorithm, in particular, using the statistical package JAGS (Plummer 2007, 2014)

in R (R Core Team 2016). Each model used 80000 MCMC samples plus a 5000 sample burn-in period. Posteriors were inspected for adequate mixing and convergence.

4.3 Multi-Model Inference

In the regression analyses, there were a high number of plausible explanatory covariates which could influence population density (time, location, time-of-day, season, etc.), but only a small amount of survey data. In such situations, it is common in ecological studies to employ “multi-model inference” (Johnson and Omland 2004). This technique was used in previous reports, and the technique is summarised here.

Briefly, the core idea is that one never knows which subset of covariates are “best” *a priori*, and so a prediction-based criteria, such as the corrected Akaike Information Criteria (AIC/AICc; Akaike 1974, 1998, Hurvich and Tsai 1989) or the Watanabe-Akaike Information Criteria (WAIC; Watanabe 2010)(Watanabe 2010)(Watanabe 2010), are useful to weight models and combine their estimates according to each models’ predictive performance. Specifically for the Bayesian models, the model-averaging uses model-weights based on the WAIC criterion (Watanabe 2010, Link and Sauer 2015):

$$p(m|\mathbf{y}) \approx \frac{e^{-0.5\text{WAIC}^{(m)}}}{\sum_m^M e^{-0.5\text{WAIC}^{(m)}}}$$

where m indexes a particular model with its own unique specification of covariates β_m .

Model-averaging is important because some models are bad at prediction because they are *overfitting* the data (they have too many covariates with too little data) and some models are *underfitting* the data (they omit an important covariate). Using a predictive criteria like the WAIC or AICc helps find the best combination of parameters which yield the highest predictive accuracy, while minimising the influence of spurious covariates.

There were 280 possible models, which included various combinations of the following:

1. a night-time vs. day-time effect, or not;
2. a radial vs. line-transect effect, or not;
3. a season-effect, or not;
4. a log-linear trend vs. no trend vs. each year has its own density; and
5. 5 different amounts of over dispersion (excess count-variation).

As mentioned in Section 3.1, there was a slight modification the analyses regarding the specification of (4) “each year has its own density”: in prior years, this meant that each years’ density was independently estimated, but there was no explicit trend. The growing availability of data and number of years allows us to incorporate both a trend-component and an inter-annual variability component, and estimate them jointly i.e., the years’ densities vary around a main trend.

Previously, with fewer years and fewer data-points, this type of model would be over-determined and unestimable. It is preferable to use this model going-forward because it better reflects reality.

4.4 Hypothesis Testing

Objectives #2 and #3 pertained to evaluating hypotheses, such as: whether there was a trend, and whether there was a night-time vs. day-time effect.

As was developed in previous reports, these hypothesis-type objectives were addressed through a Bayesian quantitative technique called posterior odds-ratios (also known as Bayes Factors; Jeffreys 1961, Kass and Raftery 1995).

The odds ratios are calculated by taking the ratio of two quantities, which, respectively, represent the strength of support for a hypothesis H_1 vs. its complimentary alternative hypotheses H_0 (i.e., a “null-hypothesis” of no effect). In this report, we used the sum of WAIC model probabilities for those models that supported the H_1 (the numerator of the odds-ratio), vs. those models that constituted the null hypothesis (the denominator of the odds-ratio). For example, the odds-ratio in favour of a trend would be:

$$BF_{\text{trend} > \text{no trend}} \approx \frac{\sum_{k \in \mathcal{M}_{\text{trend}}} \text{WAIC}_k}{\sum_{k \in \mathcal{M}_{\text{no trend}}} \text{WAIC}_k}$$

where $\mathcal{M}_{\text{trend}}$ represents the set of models that included a trend, and $\mathcal{M}_{\text{no trend}}$ represents models without a trend (which thereby act as a composite null hypothesis). The BF ratio must be substantially greater than 1 to provide evidence in favour of a trend. A BF of ~ 1 suggests that there is no meaningful difference between the H_1 and its compliment. A $BF \ll 1$, suggests strong refutation of the existence of a trend.

Similarly, another analysis used Bayesian odds-ratios to evaluate the evidence in favour of *no* night-time effect vs. evidence of a difference between night-time and day-time surveys.

As was done in previous reports, the strength of the odds-ratios were evaluated against established quantitative cut-offs (Jeffreys 1961, Kass and Raftery 1995). For instance, a ratio above 10:1 is considered “strong” evidence in favour of a trend; a ratio above 3.2:1 is “substantial” evidence; and a ratio between 3.1:1 to 1:1 is considered “barely worth a mention”.

4.5 Prospective Power Analysis

The power analysis used the same Monte Carlo simulation method as in the Year 1 report. The goal of the power analyses was to estimate the rate of Type-II errors (falsely rejecting the hypothesis of a trend, $H_a: \beta_t \neq 0$) while simultaneously detecting a 30% decline from baseline levels at Broadwater and Bagotville, between years 2015 to 2031. The error rates were conditional on:

1. a negative trend of -30% from baseline levels until Year 15 of monitoring;
2. a cap on the rate of Type-I errors at $\alpha \leq 0.3$;
3. monitoring effort of 400 transects per year per location (Broadwater and Bagotville separately);
4. marginal effects for other independent covariates (such as day-time/night-time, spring/autumn, and line-transect/radial-search transects) empirically derived from the Bayesian estimation analysis (from Objective #1); and

5. baseline koala densities in 2015 derived from the Bayesian estimation analysis.

A key-point to note is item (4): notice how the Monte-Carlo procedure incorporates several sources of empirically-derived uncertainty. First, there is the uncertainty in the baseline densities at Bagotville and Broadwater, as quantified by the posterior distributions of Year 0 densities from the Bayesian estimation exercise (Objective #1). Secondly, there is the uncertainty in the magnitude of marginal effects (such as day-time/night-time, spring/autumn, and line-transect/radial-search). This uncertainty was incorporated by using the posterior distributions from the Bayesian estimation exercise. Finally, there is the *multi-model* uncertainty due to multiple plausible models for estimating statistical power. The latter point reflects the fact that a future analyst will want to improve their statistical accuracy by including or excluding certain covariates, and will likely perform model-selection by AIC (Akaike 1974, 1998).¹

These three sources of uncertainty make the calculation of Type-II errors non-trivial. They are best estimated through Monte Carlo simulations. This Monte Carlo power analysis proceeded as follows:

1. set the annual percent decline to $-\delta$, and set parameters $\beta_t = \log(1 - \delta)$, $\beta_{t,bw} = 0$,
2. set the desired Type-I error rate to α ;
3. for i in 1 to 4000 Monte Carlo iterations, do:
 - I. get a sample of parameter values from the Bayesian posteriors (e.g., baseline densities, over dispersion, marginal effects of day-time/night-time, spring/autumn, and line-transect/radial-search) $\beta_{-t}^{(i)} \sim \pi(\beta_{-t} | \mathbf{y})$, $\theta^{(i)} \sim \pi(\theta | \mathbf{y})$, and combine these samples with the specified trend in (1) above: $\beta^{(i)} = (\beta_{-t}^{(i)}, \beta_t, \beta_{t,bw})^T$;
 - II. simulate count data \mathbf{y} using the linear model in Eqn. 1 and parameters $\beta^{(i)}$

$$y_{l,t,j}^{(i)} \sim \text{NB}\left(e^{(\mathbf{x}_{l,t,j} \beta^{(i)} + \log(p_d \cdot A_{l,t,j}))}, \theta^{(i)}\right);$$
 - III. use the simulated data $\mathbf{Y}^{(i)}$ to get maximum-likelihood estimates of the trend and standard error $(\hat{\beta}_t^{(i)}, \hat{\text{se}}(\beta_t)^{(i)})$ for both Broadwater and Bagotville, including:
 - i. option 1: use the Poisson *full-model* (model m_8 in Eqn. 2), or
 - ii. option 2: use the best AIC Poisson model from models m_1 to m_8
 (this analysis proceeded with option 2, but I also ran option 1 for comparison purposes)
 - IV. for each location l (Broadwater and Bagotville) compare the two-tailed Fisher p-value to α and calculate the score statistic l

¹ Note: in the future, there will be a lot of data, which will make the difference between the AICc vs AIC unimportant. The AICc is a correct for small-sample sizes, and converges to the AIC with increasing data.

$$I_l^{(i)} = 2 \left(1 - \text{PDF}_{\mathcal{N}} \left(\frac{|\hat{\beta}_t^{(i)}|}{\hat{\text{se}}(\beta_t)^{(i)}} \right) \right) \leq \alpha$$

Over all 4000 iterations, the estimated Type-II error rate (per / location Broadwater and

Bagotville) was $\hat{b}_{l,\alpha,\beta_t} \approx \frac{1}{4000} \sum_{i=1}^{4000} I_l^{(i)}$ and the power is $1 - \hat{b}_{l,\alpha,\beta_t}$

4.6 Supplemental Analyses

The Year 2 report (Sandpiper Ecological 2019b) introduced several supplementary analyses that were continued in the Year 3 and Year 4 studies. These supplementary analyses were meant to investigate alternative methods of estimating trends and evaluating evidence for or against the presence of a trend. These supplements varied according to the hypothetical strength of prior information, and merely helped to contextualise the main results. The present report continued with only one such supplementary technique which used the AICc as a model-averaging criteria to get an alternative indicator of a trend that is more sensitive to changes.

4.6.1 Estimation According to AICc Model-Averaging

This analysis used frequentist Negative-Binomial GLMs and performed model-averaging by AICc weights (Akaike 1974, 1998, Schwarz 1978) to estimate the trends at Broadwater and Bagotville. As described in the Year 2 report, these models can be thought of as pseudo-Bayesian models whereby i) the priors-on-parameters have been weakened to zero-influence, and ii) priors-on-model-probabilities are adaptive (i.e., they become more conservative with less data, and more liberal with more data). In other words, the AICc “reacts” faster to new data compared to static Bayesian priors used in the main analyses.

The trade-off is that while the AICc may be more sensitive to developing trends, it may result in some overfitting and be alarmist, as compared to the Bayesian models with stronger priors. See the Year 2 report (Sandpiper Ecological 2019b) for more discussion on the difference between the Bayesian-WAIC models and the frequentist-AICc models.

4.6.2 Hypothesis Testing According to AICc-Evidence Ratios

In the same way that one can garner evidence for or against a hypothesis according to Bayesian posterior odds-ratios (see above), the sum-of-AICc weights can also be used to produce odds-ratios (Lukacs et al. 2007). The AICc-based odds-ratios are analogous to the WAIC-based Bayes Factors but are simply called “evidence” ratios, according to the “Evidentialist” approach (Taper and Ponciano 2016). The interpretation is largely the same as for the Bayesian approach: high ratios > 1 are evidence in favour of a trend vs. no trend (except that the AICc controls Type-I errors more consistently across sample sizes, Taper and Ponciano 2016). The sum-of-AICc ratios was used to assess the evidence in favour of a trend vs. no-trend, to supplement the Bayesian odd-ratios.

5 Results

5.1 Descriptive Statistics

The following are descriptive summaries about the observed counts and (unmodelled) densities of koalas at Broadwater and Bagotville. Both time-series seem to reveal a decrease in counts and densities at both locations compared to Year 3, but approximately the same values as was seen in Year 2.

Table 1: Empirical total counts aggregated per year and location

Location	Baseline	Year 1	Year 2	Year 3	Year 4
Broadwater	8	13	5	15	7
Bagotville	4	17	18	22	16

Table 2: Empirical densities (koalas/ha), pooled, per year and location

Location	Baseline	Year 1	Year 2	Year 3	Year 4
Broadwater	0.117	0.053	0.013	0.069	0.018
Bagotville	0.093	0.069	0.077	0.063	0.051

5.2 Results for Objective #1: Density Estimation

The following tables show the updated estimates for all years, segregated by location and season. Table 3 shows pooled estimates; Table 4 shows seasonal estimates. The estimates were calculated by model-averaging according to WAIC model probabilities.

Broadwater continues to show a decrease in densities (although the 95%CI are strongly overlapping), whereas Bagotville continues to show little-to-no trend.

Table 3: Bayesian estimates densities (koalas/ha), pooled, per year and location

Location	Baseline	Year 1	Year 2	Year 3	Year 4
Broadwater	0.060 (SE: 0.012; CI: 0.040-0.086)	0.054 (SE: 0.009; CI: 0.039-0.072)	0.051 (SE: 0.008; CI: 0.036-0.067)	0.049 (SE: 0.008; CI: 0.035-0.066)	0.046 (SE: 0.008; CI: 0.032-0.065)
Bagotville	0.081 (SE: 0.014; CI: 0.057-0.111)	0.080 (SE: 0.011; CI: 0.061-0.102)	0.080 (SE: 0.010; CI: 0.061-0.101)	0.081 (SE: 0.011; CI: 0.060-0.104)	0.080 (SE: 0.012; CI: 0.058-0.106)

Table 4: Bayesian estimates of densities (koalas/ha), per year and season

Location	Base-line	Year 1 Spring	Year 1 Autumn	Year 2 Spring	Year 2 Autumn	Year 3 Spring	Year 3 Autumn	Year 4 Spring	Year 4 Autumn
Broadwater	0.060 (SE: 0.012; CI: 0.040- 0.086)	0.054 (SE: 0.009; CI: 0.038- 0.073)	0.054 (SE: 0.009; CI: 0.038-0.073)	0.051 (SE: 0.008; CI: 0.036- 0.068)	0.051 (SE: 0.008; CI: 0.036- 0.068)	0.049 (SE: 0.008; CI: 0.034- 0.067)	0.049 (SE: 0.008; CI: 0.034- 0.067)	0.047 (SE: 0.009; CI: 0.031- 0.066)	0.046 (SE: 0.009; CI: 0.031- 0.065)
Bagotville	0.081 (SE: 0.014; CI: 0.057-0.111)	0.081 (SE: 0.011; CI: 0.060-0.105)	0.080 (SE: 0.011; CI: 0.060- 0.103)	0.081 (SE: 0.011; CI: 0.060-0.104)	0.080 (SE: 0.011; CI: 0.060- 0.102)	0.081 (SE: 0.012; CI: 0.059-0.105)	0.081 (SE: 0.011; CI: 0.059-0.104)	0.081 (SE: 0.013; CI: 0.058-0.108)	0.080 (SE: 0.013; CI: 0.057-0.107)

5.2.1 Supplementary Analysis: AICc-based model-averaged model estimates

Table 5 shows the supplementary density estimates using AICc-based model weights to produce model-averaged estimates. The method reveals a decrease in koala density in Year 4 compared to Year 3 and Year 2, at both locations.

Table 5: AICc-based estimates of densities, by year and location.

Location	Baseline	Year 1	Year 2	Year 3	Year 4
Broadwater	0.105 (SE: 0.053; CI: 0.055- 0.259)	0.061 (SE: 0.015; CI: 0.033-0.093)	0.045 (SE: 0.017; CI: 0.010-0.066)	0.045 (SE: 0.020; CI: 0.027-0.101)	0.032 (SE: 0.012; CI: 0.016-0.062)
Bagotville	0.082 (SE: 0.040; CI: 0.033-0.183)	0.081 (SE: 0.018; CI: 0.048-0.121)	0.080 (SE: 0.017; CI: 0.049-0.116)	0.082 (SE: 0.020; CI: 0.056-0.135)	0.077 (SE: 0.019; CI: 0.042-0.115)

5.3 Objective #2: Emerging Trends

5.3.1 Trend Estimate

The estimated log-linear trend at Broadwater was $-0.033/\text{year}$ (SE: 0.043; 95%CI $-0.127-0.028$), i.e. 3.3% decline per year, with a 0.756 posterior probability of decline. This is approximately double the decline that was estimated during the 2019/20 Year 3 report (which was -0.016 per year).

The estimated log-linear trend at Bagotville was $-0.000/\text{year}$ (SE: 0.025; 95%CI $-0.061-0.060$), with a 0.488 posterior probability of a decline. This is nearly the same as the prior year's estimate of 0.001/year.

5.3.2 Trend Hypothesis-Testing

The trend at Broadwater had a posterior odds ratio (Bayes Factor) of 2.071 in favour of a trend vs. no-trend. This is slight evidence that there was a trend. This is nearly double the Bayes Factor that was estimated in the previous report (1.172), but is nonetheless considered 'barely worth mentioning' (Jeffreys 1961, Kass and Raftery 1995).

The trend at Bagotville had a posterior odds ratio (Bayes Factor) of 0.782, which is slightly lower than last year's estimate of 0.847. It is slight evidence *against* there being a trend. This ratio falls into the conventional descriptive bin 'barely worth mentioning'.

5.3.3 Supplementary Trend Analysis by AICc Model-Averaging

According to the frequentist AICc-based model-averaged estimates, the estimated log-linear trend at Broadwater was $-0.218/\text{year}$ (SE 0.131), i.e., a 21.8%/year decline. Despite the extreme trend, it is less extreme than the trend produced during the Year 3 report, which was estimated to be $-0.259/\text{year}$ (SE: 0.177). The variance was so high that the hypothesis testing statistics do not provide overwhelming evidence in favour of a trend: the AICc-based odds-ratio in favour of a trend at Broadwater was 2.563 which is 'barely worth mentioning' (but is more than double the evidence estimated from the Year 3 report, which was 0.966). The Fisher p-value against a trend was 0.094, which is much lower than the prior year's estimate of 0.145, and is moving in the direction of rejecting the "no trend" null-hypothesis.

The estimated AICc-based log-linear trend at Bagotville was $-0.006/\text{year}$ (SE: 0.085), i.e., a 0.6% decline per year. For both the absolute magnitude of the trend and its uncertainty, both values were lower than the Year 3 estimates of $0.042/\text{year}$ (SE: 0.123). At Bagotville, the AICc-based odds-ratio in favour of a trend was 0.155, which is 'barely worth mentioning', and less than half the evidence from the Year 3 report (0.389). The Fisher p-value against the no-trend null-hypothesis was 0.945 (i.e., cannot reject the no-trend null-hypothesis).

5.4 Objective #3: Day-Time vs. Night-Time Effect

A posterior odds-ratio (Bayes Factor) was employed to determine whether night-time surveys yielded meaningfully different densities than day-time surveys. In this case, the favoured hypothesis of *no*-difference constitutes the numerator of the odds-ratio, and the alternative hypothesis of *yes*-difference constitutes the denominator. Therefore, odds-ratios values above 1 support the conjecture that there is *no* difference between night-time and day-time surveys, and values <1 support the conjecture that there *is* a night-time effect.

The posterior odds-ratio was 2.141, i.e., there was some slight evidence against the presence of a night-time effect. This estimate was approximately 60% higher than the Year 3 estimate of 1.369. This ratio is within the ratio-category which is conventionally described as "barely worth mentioning" (Kass and Raftery 1995).

5.5 Objective #4: Prospective Power Analysis

The results of the prospective power analysis are showing in figure 1.

For a maximum Type-I error rate of 0.3, the estimated power for Bagotville and Broadwater were 0.726 and 0.667 respectively. These are slight improvements upon the estimates from the previous year's report of 0.695 and 0.661 respectively.

For a maximum Type-I error rate of 0.35, the estimated power for Bagotville and Broadwater were 0.764 and 0.700 respectively, both of which are as good or better than the estimates from the Year 3 report.

The Bayes' p-values for Bagotville and Broadwater were 0.945 and 0.919, which improved upon the Year 3 report estimates of 0.928 and 0.916 respectively. ²To interpret these values, it means that if there was a 30% decline, a Bayesian analyst would be able to conclude that there was a trend with 94.5% certainty at Bagotville, and likewise 91.6% certainty at Broadwater. In other words, there is more certainty about the Bagotville system than there is at the Broadwater system.

6 Discussion and Conclusions

This report presents a quantitative assessment of the Year 4 (2020/21) W2B Pacific Highway upgrade koala population monitoring program at Bagotville (section 10) and Broadwater (section 8/9).

Overall, there is increasing evidence of a negative population trend at Broadwater and a stable population at Bagotville, even though the latter did have lower empirical counts and densities compared to Year 3.

Measures of power and statistical certainty remain low but are improving.

6.1 Trends and Densities

At Bagotville, the pooled Year 4 density was 0.080 koalas/ha (SE: 0.012; CI: 0.058-0.106), which shows no difference from the Year 3 density 0.081 (SE: 0.011; CI: 0.060-0.104). The per-year densities have lower overall standard-errors, suggesting improving certainty in the estimates. There is no evidence of a trend, which was estimated to be 0.000%/year and had a high frequentist p-value. Compared to the Year 3 report, there is increasing confidence that Bagotville has little to no trend.

Overall, at Broadwater, the estimated densities were lower and the downward trend was more pronounced. The estimate of the Year 4 density at Broadwater was 0.046 koalas/ha (SE: 0.008; CI: 0.032-0.065), which was lower than the preceding years. The estimated trend (-3.3%/a) was double the magnitude of the Year 3 analysis (-1.6%/year). However, given the uncertainty in the estimates, the Bayes Factors do not provide strong evidence of a decline.

A supplemental analysis using frequentist model-averaging and Fisher p-values likewise do not provide strong evidence against the no-trend hypothesis ($p=0.094$). However, the p-value is smaller than the Year 3 estimate of $p=0.145$. If the Broadwater population density in Year 5 is similar to or smaller than the Year 4 density, it could be that the future Year 5 p-value will reach the conventional cut-off of 0.05 (i.e., a 95% Type I error rate), at which point one will no longer be able to reject the null-hypothesis of "no trend".

6.2 Night-Time Effects

This report revisited the question about whether there was a meaningful difference between night-time vs. day-time surveys. In previous reports, the odd-ratio statistic provided slight evidence *against* a night-time effect (Year 2: 2.21; Year 3:1.369). Based on the updated data from Year 4, this statistic is close to its previous

² Frequentists are concerned about capping the Type-I error rate below some threshold, then maximizing the power (minimising the Type-II error rate), whereas Bayesian merely want the probability of a decline.

value at 2.141. In other words, there seems to be little concern that night-time surveys are providing materially different information compared to day-time surveys.

6.3 Prospective Power Analysis

The latest update to the prospective power analysis suggests that Bagotville has a statistical power that is above the 0.7 target at 0.726. Broadwater had an estimated power of 0.667 which is slightly higher than the Year 3 estimate of 0.661, but still below the 0.7 target.

The improvements in statistical power has not been as large as the improvements in other statistical measures, such as declining p-values or reductions in standard errors of density estimates. As mentioned previously, the statistical power is sensitive to the overall uncertainty in the entire system, because it incorporates empirical estimates of variance in the MCMC routine. It may be that more transects will have to be conducted in order to meaningfully improve the power at Broadwater.

6.4 Final Thoughts

Overall, there remains a high-level of statistical uncertainty across various measures, such as the standard errors of density estimates, the high p-values of trend estimates, the moderate power-levels for the prospective power analyses, and the low evidence ratios for Bayesian hypothesis tests.

These measures have improved since the Year 3 report with the addition of the Year 4 data. However, the additional data did not create a large boost in statistical certainty to detect what appears (according to the raw numbers) to be a large negative trend at Broadwater. More years of data-collection will alleviate this problem, but more within-season transects may be what is ultimately necessary to get stronger power and adequate statistical certainty.

Finally, one should keep in mind some of the findings of the Year 2 supplementary analyses (Sandpiper Ecological 2019b) which studied the degree of conservativeness vs sensitivity of the different trend-detection statistics (such as the frequentist p-values, the Bayes Factor, and AICc-evidence ratios). Those Year 2 supplementary studies concluded that the Bayes Factor was the most conservative, followed by the frequentist p-values, and the AICc-evidence ratio was the most sensitive. In keeping with those results, the AICc-evidence ratio method was the first (in Year 2) to declare a trend at Broadwater, and the frequentist p-values are getting close to declaring a trend, while the Bayes Factor method continues to find no evidence of a trend.
